

HEAT TRANSFER SHEET, IMAGE FORMING MATERIAL, AND IMAGE FORMING METHOD

5

FIELD OF THE INVENTION

This invention relates to a heat transfer sheet, an image forming material, and an image forming method which are used to form a full color image of high resolution with laser light.

10 More particularly, the invention relates to a heat transfer sheet, an image forming material, and an image forming method which are useful to obtain a direct digital color proof (DDCP) in the field of printing or a mask image based on digital image signals by laser recording. The invention also relates to a
15 heat transfer sheet material applicable to on-demand image recording and to an on-demand image forming method.

BACKGROUND OF THE INVENTION

20

In the field of graphic arts, a printing plate is produced using a set of color separation films of a color original which are prepared using lithographic films. In general, a color proof is prepared from color separation films in order to inspect
25 for errors in color separation and to check the need for color

correction and the like before going to press. With the recent spread of computerized systems in prepress work, recording systems for preparing color proofs directly from digital signals, i.e., DDCP systems have been developed.

5 the advancement of desk-top publishing (DTP) environment, printing companies adopting a computer-to-plate (CTP) system have a strong demand for a DDCP system, which eliminates the need of intermediate film or plate output as has been involved in traditional analog proofing. In recent years, DDCPs with
10 higher quality, higher stability, and larger sizes have been demanded as good approximations to the final prints.

Such computerized systems, particularly contemplated for preparing high quality color proofs, generally use as a recording head a laser beam which is capable of modulation according to
15 digital signals and focusing into a small spot diameter to reproduce dot images at 150 lines or more per inch.

Laser thermal transfer systems using a heat transfer sheet are capable of image formation at high resolution. The heat transfer sheet generally has, on a substrate, a light-heat
20 conversion layer containing a light-heat converting substance capable of converting laser energy to heat, an image forming layer containing a colorant, and other optional layers such as a heat-sensitive release layer. Known laser thermal transfer systems include (1) laser sublimation, (2) laser ablation (see
25 JP-A-6-219052), and (3) laser melt (see JP-A-5-58045). These

image forming methods are advantageous in that stock paper having an image receiving layer (adhesive layer), which is actually used in printing, can be used as an image receiving material and that a multicolor image can easily be obtained by successively transferring images of different colors to an image receiving sheet. The methods furnish highly precise images with ease and are useful to prepare color proofs or high precision mask images. However, all these thermal transfer systems cannot get rid of the problem that the recorded dot shape is not sharp enough. Specifically, the laser sublimation system is insufficient in approximation in color to the final print results because of use of dyes as coloring matter. Besides, this system involving dye sublimation results in blurred dot outlines, failing to achieve sufficiently high resolution. The laser ablation system, which uses pigments as coloring matter, provides a satisfactory approximation in color to the final printed products. However, because of the involvement of coloring matter's scattering, the dots are blurred, resulting in insufficient resolution similarly to the dye sublimation system. The laser melt system also fails to create clear dot outlines because the molten colorant flows.

In addition to the above-described systems, a thin film transfer system using laser light has recently been proposed as means for transferring dots with clear outlines to give a transfer image of high resolution and high quality (see

JP-A-2002-274051)

The layers constituting image forming materials used in the laser transfer system are generally formed using organic solvent type coating compositions. Nevertheless, waterborne coating compositions containing an aqueous binder are preferred for environmental considerations. With reference to heat sensitive transfer recording media having a release layer and a heat softening layer, such as an ink ribbon for thermal transfer, it is known that the heat softening layer can be provided by using a waterborne coating composition containing an aqueous binder (see JP-A-63-193886). However, no proposal has been made for an aqueous binder capable of forming an image forming layer with excellent performance as an image forming material according to a laser thermal transfer system.

Recently, on-demand printing by laser thermal transfer has been desired, in which a precise quantity of a heat transfer sheet is prepared when needed. On-demand printing utilizing an ink jet system or an electrophotographic system is known as means for providing more diversified customized service with smaller production lots (see JP-A-2002-154724). On-demand printing technology using a laser thermal transfer system for DDCPs has not been proposed as yet.

SUMMARY OF THE INVENTION

An object of the present invention is to provide a heat transfer sheet which is prepared by using an aqueous binder
5 and yet provides a high quality image at high sensitivity.

Another object of the invention is to provide a multicolor image forming material and a multicolor image forming method, with which to provide a high quality, high stability, and large size DDCP serving as a good approximation of final printed
10 products.

Still another object of the invention is to provide a multicolor image forming material and a multicolor image forming method, with which to form a high quality image on an image receiving sheet with a stable transfer density even in
15 high-energy laser recording with a multibeam laser writing system under varied temperature and humidity conditions.

Yet another object of the invention is to provide an image forming material and an image forming method which can provide a DDCP on demand.

20 To accomplish the above objects, the present invention provides, in its first aspect, a heat transfer sheet comprising a substrate having thereon at least a light-heat conversion layer and an image forming layer. The image forming layer contains as a binder an acrylic resin and/or a styrene-acrylic
25 copolymer resin. The acrylic resin and the styrene-acrylic

copolymer resin have a glass transition temperature (T_g) of 50°C or lower and a minimum film-forming temperature (MFT) of 50°C or lower.

5 The heat transfer sheet preferably has an intermediate layer farther from the substrate than the light-heat conversion layer.

The present invention also provides, in its second aspect, an image forming material comprising an image receiving sheet having an image receiving layer and the heat transfer sheet according to the present invention. The heat transfer sheet is adapted to be superposed on the image receiving sheet with the image forming layer facing the image receiving layer and irradiated with laser light to transfer the irradiated area of the image forming layer to the image receiving layer to record
10 an image on the image receiving sheet.
15

The image recorded by using the image forming material preferably has a size of 515 mm by 728 mm or larger.

The present invention also provides, in its third aspect, a method of forming an image by using the image forming material according to the invention. The method includes the steps of
20 superposing the heat transfer sheet of the invention on the image receiving sheet with the image forming layer of the heat transfer sheet facing the image receiving layer of the image receiving sheet, imagewise irradiating the superposed heat
25 transfer sheet with laser light, and transferring the irradiated

area of the image forming layer to the image receiving layer of the image receiving sheet in the form of a thin film to record an image.

The present invention also provides, in its fourth aspect,
5 a coating composition for forming an image forming layer on a laminate sheet comprising a substrate, a light-heat conversion layer, and an intermediate layer in this order. The coating composition is adapted to be applied to the intermediate layer on demand for image recording. The coating composition contains
10 a waterborne latex of an acrylic resin and/or a styrene-acrylic copolymer resin. The acrylic resin and the styrene-acrylic copolymer resin have a glass transition temperature (T_g) of 50°C or lower and a minimum film-forming temperature (MFT) of 50°C or lower.

15 The present invention also provides, in its fifth aspect, a method of forming an image on demand. The method includes the steps of applying the above-described coating composition to a laminate sheet to prepare a heat transfer sheet; superposing the heat transfer sheet on an image receiving sheet having an
20 image receiving layer with the image forming layer facing the image receiving layer; imagewise irradiating the superposed heat transfer sheet with laser light; and transferring the irradiated area of the image forming layer to the image receiving layer of the image receiving sheet in the form of a thin film
25 to record an image. The laminate sheet has a substrate, a

light-heat conversion layer, and an intermediate layer in this order, and the coating composition is applied to the intermediate layer of the laminate sheet.

The present inventors previously studied to provide DDCPs
5 of B2/A2 or larger sizes and even of B1/A1 or larger sizes while securing high image quality, high quality stability, and satisfactory level of approximation to a final output product. As a result, they developed a laser thermal transfer recording system for DDCP including (a) an image forming material
10 characterized by capability of image transfer to the same material as stock (printing paper), capability of outputting true halftone dots, use of pigments as a colorant, and large sizes of B2 or larger, (b) an output device, and (c) high quality CMS (content management system) software. The performance
15 features, system configuration, and technical key points of the laser thermal transfer recording system developed by the inventors are as follows. The performance features reside in (1) sharp dot formation, which offers a good approximation to final prints, (2) a satisfactory level of approximation in hue
20 to final prints, and (3) stable proof quality owing to performance stability against variations of the environment (i.e., temperature and humidity) and repetition.

From the aspect of material design, technical key points that make this system work are establishment of thin film
25 transfer technology and improvements on the heat transfer

elements' capability of being tightly held on a recording drum by suction, capability of high-resolution recording, and heat resistance. More specifically, the developed thermal transfer recording system has been realized by (i) introduction of an infrared absorbing colorant, which permits thickness reduction of a light-heat conversion layer, (ii) introduction of a high-Tg polymer, which enhances heat resistance of a light-heat conversion layer, (iii) introduction of a heat-resistant pigment, which leads to hue stabilization, (iv) addition of a low-molecular component, such as a wax and an inorganic pigment, which controls adhesion and cohesion, and (v) addition of a matting agent to a light-heat conversion layer, which ensures intimate contact to an image receiving sheet without causing image quality deterioration. From the aspect of apparatus design, on the other hand, technical key points that make this system work lie in (vi) an air ejection system adopted to a laser recording apparatus, with which a plurality of image receiving sheets having received an image can be stacked, (vii) the manner of inserting a sheet of printing paper and an image receiving sheet into a thermal transfer apparatus, in which the printing paper is superposed on the image receiving sheet placed with its image side up, which manner is effective to prevent the printing paper from curling after heat transfer, and (viii) connection to a general-purpose output drive which allows broadening of system configuration freedom. Thus, the

laser thermal transfer recording system for DDCP the inventors developed is integration of various performance characteristics, system configuration, and the technical key points. This recording system is an illustrative example of means for carrying out the image forming method of the invention, and the present invention is not deemed to be limited thereto.

Material factors such as combinations of image forming elements (i.e., heat transfer sheets and an image receiving sheet), constituent layer configurations (e.g., a light-heat conversion layer, an image forming layer, and an image receiving layer), formulation of each element, and the like are not to function dependently but to be organically linked with each other. Furthermore, these image forming elements are to play their best performance when linked with a recording apparatus and a thermal transfer apparatus. The present inventors have continued their study based on this concept. They have thoroughly examined each layer of the image forming elements (inclusive of the transfer sheet and the image receiving sheet) and materials making up the layers. They have designed the layers constituting the image forming elements so that the constituent materials may be allowed to show their characteristics to the full. They have found proper ranges of various physical properties within which the image forming elements exert their full characteristics. As a result, the inventors have found out the best relations between physical

properties and performance of the materials, layers, and sheets and succeeded in developing an image forming material which exhibits unexpectedly high performance when organically and systematically linked with a recording apparatus and a thermal
5 transfer apparatus.

Significance of the present invention in the above-mentioned system developed by the inventors resides in offering an image forming material fit for the above-described system. In particular, the present invention is of high
10 importance, providing a heat transfer sheet which has an image forming layer containing an aqueous binder and yet exhibits high sensitivity and high image quality, an image forming material including the heat transfer sheet, and an image forming method using the image forming material. The present invention
15 is also of high value, providing a material and a method for image formation fit for on-demand printing for obtaining DDCPs in needed quantities when needed.

20 BRIEF DESCRIPTION OF THE DRAWINGS

5

DETAILED DESCRIPTION OF THE INVENTION

The heat transfer sheet according to the invention
10 contains in the image forming layer thereof an acrylic resin
and/or a styrene-acrylic copolymer resin both of which have
a Tg of 50°C or lower, preferably 20°C or lower, and a minimum
film-forming temperature (MFT) of 50°C or lower, preferably
20°C or lower, as a binder. The binder is, while being aqueous,
15 capable of forming an image forming layer with a satisfactory
coating surface condition, and the resulting heat transfer sheet
is capable of providing a high quality image at high sensitivity.

The image forming layer is formed by applying a coating
composition containing a waterborne latex of the above-defined
20 aqueous binder. The terminology "waterborne latex" as used
herein denotes a system which is composed of a continuous phase
containing water as a main solvent and a prescribed resin
emulsified or suspended in the continuous phase as a disperse
phase and which dries to form a film. Disperse systems which
25 dry to form a film, such as waterborne emulsions and aqueous

colloids, will be included under the category "waterborne latex". The waterborne latex used in the invention is not limited in process of preparation.

5 The coating composition for forming an image forming layer comprises not only the specified waterborne latex but a pigment described later and, if desired, other components including a wax and a plasticizer.

10 The thickness of the image forming layer of the heat transfer sheet is preferably 1.5 μm or smaller, still preferably 0.9 μm or smaller. The lower limit of the thickness is usually about 0.2 μm .

15 It is desirable for the image forming layer of the heat transfer sheet to have an optical density (OD_I) to thickness (T_I ; unit: μm) ratio, OD_I/T_I , of 1.6 or higher, preferably 1.8 or higher, still preferably 2.50 or higher. The higher the ratio, the more desirable. Taking the balance with other characteristics into consideration, however, the upper limit of the ratio would be about 6 for the time being. The OD_I/T_I is a measure of transfer image density of the image forming
20 layer and the resolution of the transfer image. The OD_I/T_I being in the recited range, a transfer image with a high density and a high resolution can be produced. A thinner image forming layer brings about increased color reproducibility.

25 The heat transfer sheet has a light-heat conversion layer on the substrate independently of the image forming layer to

control color change and to assure color reproducibility.

The light-heat conversion layer preferably contains a polyamide-imide resin binder and a cyanine dye having a sulfonic acid group. A cyanine dye having a sulfonic acid group is characterized by high stability and insusceptibility to decomposition. When combined with a polyamide-imide resin binder, the cyanine dye is also characterized by its high affinity to the polyamide-imide resin so that it is prevented from migrating into the image forming layer, thereby suppressing color change between before and after the transfer to an image receiving layer. A combination of the polyamide-imide resin binder and the cyanine dye is also effective in assuring excellent stability of a coating composition for the light-heat conversion layer with time.

It is preferred for the light-heat conversion layer to have a surface gloss of 85 or higher, particularly 85 or higher and lower than 100, as represented in terms of Gs (60°C) specified in JIS Z8741. With the surface gloss of the light-heat conversion layer adjusted within the above range, the image forming layer will have controlled surface properties to have adequate adhesion to an image receiving layer thereby providing good image quality. The surface gloss of the light-heat conversion layer can be adjusted by, for example, selection of the kind and amount of the matting agent to be added.

The difference in water content between the image forming

layer and the image receiving layer of an image receiving sheet is preferably as small as possible. Specifically, the absolute difference in water content between these two layers at 19°C and 30% RH is preferably 1.0% by weight or smaller, still preferably 0.5% by weight or smaller. It is also preferred that the absolute difference between the water content of the image forming layer at 19°C and 30% RH and that of the image receiving layer at 27°C and 70% RH be 1.0% by weight or smaller, particularly 0.5% by weight or smaller. These water contents are calculated from the weight difference between a subject layer having been conditioned in the recited atmosphere and the subject layer having been dried.

With the water content difference being in the above ranges, a better quality image can be produced in a more stable manner.

The film strength of the image forming layer is preferably such that the image forming layer having been transferred to an image receiving layer has a film strength of 200 g or higher as measured with a scratch tester. With this condition satisfied, the image on the image receiving sheet can be re-transferred to printing paper in a stable and successful manner.

It is desirable for the light-heat conversion layer of the heat transfer sheet to have an optical density (OD_{LH}) to thickness (T_{LH} ; unit: μm) ratio, OD_{LH}/T_{LH} , of 4.36 or higher. The higher the ratio, the more desirable. Taking the balance

with other characteristics into consideration, nevertheless, the upper limit of the ratio would be about 10 for the time being.

The OD_{LH} of the heat transfer sheet refers to the absorbance
5 of the light-heat conversion layer at the peak wavelength of laser light used for recording. The absorbance is measured with a known spectrophotometer. A UV spectrophotometer "UV-240" supplied by Shimadzu Corp. was used in the invention. The OD_{LH} is obtained by subtracting the optical density of the
10 substrate from that of the laminate composed of the substrate and the light-heat conversion layer.

The OD_{LH}/T_{LH} relates to thermal conductivity in recording and is a measure greatly influential on the sensitivity and temperature- and humidity-dependence of recording. With the
15 OD_{LH}/T_{LH} falling within the above-recited preferred range, the sensitivity of transfer to the image receiving sheet is increased, and recording dependence on environmental temperature and humidity is reduced. Specifically, the OD_{LH}/T_{LH} of 4.36 or higher provides a transfer image at a high resolution preferably of
20 2400 dpi or more, still preferably of 2600 dpi or more, and over a wide area as referred to *infra*.

The thickness T_{LH} of the light-heat conversion layer is preferably 0.03 to 1.0 μm , still preferably 0.05 to 0.5 μm .

It is preferred for the image forming layer of the heat
25 transfer sheet and the image receiving layer of the image

receiving sheet to have a water contact angle of 7.0° to 120.0° , particularly 30.0° to 100.0° . The water contact angle is a measure of compatibility between the image forming layer and the image receiving layer, namely, transfer capabilities. In particular, the water contact angle of the image receiving layer is desirably 86° or smaller. With the contact angles falling in the recited ranges, the transfer sensitivity is improved, and temperature and humidity dependence of recording performance is reduced. In the invention, the water contact angles are measured with a contact angle meter CA-A supplied by Kyowa Interface Science Co., Ltd.

In the present invention, an image can be formed over a larger recording area than in conventional techniques by controlling the physical properties of the heat transfer sheet as described above. The image recording area achieved by the invention is preferably 515 mm by 728 mm (B2 size) or larger, still preferably 594 mm by 841 mm (A1 size) or larger. Accordingly, the size of the image receiving sheet is preferably 465 mm by 686 mm or larger.

As stated, the present invention provides an image forming material and an image forming method suited to on-demand production of DDCPs. The image forming material provided by the invention for on-demand applications includes a laminate sheet comprising a substrate, a light-heat conversion layer, and an intermediate layer and a coating composition for forming

an image forming layer on the laminate sheet. On demand for image recording, the coating composition is applied to the intermediate layer of the laminate sheet to prepare a heat transfer sheet.

5 The laminate sheet can be used in common for preparing various heat transfer sheets different in color of the image forming layer. When needed, a coating composition of a needed hue is applied to the laminate sheet to obtain a heat transfer sheet of the needed hue. Accordingly, it is no more necessary
10 to stock a large volume of heat transfer sheets for every color, which saves both labor and cost. The combination of the laminate sheet and the coating composition is particularly advantageous for preparing heat transfer sheets of diversified spot colors and for small production lots.

15 The total system, inclusive of the present invention, the present inventors have developed will be described hereunder. The system according to the present invention adopts the thin film thermal transfer system to accomplish high resolution and high image quality. The system is capable of producing a
20 transfer image at a high resolution of 2400 dpi or more, preferably 2600 dpi or more. The thin film thermal transfer system is such that an image forming layer as thin as 0.01 to 0.9 μm is imagewise transferred to an image receiving sheet in the state not melted or hardly melted. In other words, the
25 irradiated area of the image forming layer is transferred while

keeping its shape as thin film so that an extremely high resolution is achieved. In a preferred method for effectively carrying out thin film transfer, the light-heat conversion layer is thermally deformed into a dome shape on being irradiated.

5 The dome-shaped light-heat conversion layer pushes the image forming layer outward, whereby the image forming layer is brought into more intimate contact with the image receiving layer and transferred thereto easily. Great deformation generates a great force pushing the image forming layer toward the image

10 receiving layer and results in easy transfer. Small deformation produces only a small pushing force and fails to accomplish perfect transfer. Hence, the deformation should be quantified as a measure of transfer capabilities. In the invention, the degree of deformation is represented by a deformation percentage

15 obtained by dividing the sum of (a) the cross-sectional area of the layer after irradiation and (b) the cross-section area of the light-heat conversion layer before irradiation by the cross-section area (b) and multiplying the quotient by 100. That is, deformation percentage (%) = $\{(a + b) / (b)\} \times 100$. The

20 cross-sectional areas (a) and (b) are measured with a laser microscope VK8500 supplied by Keyence Corp. A deformation percentage preferred for thin film transfer is 110% or higher, preferably 125% or higher, still preferably 150% or higher. While the deformation percentage could exceed 250% as long as

25 the light-heat conversion layer has an increased elongation

at break, a preferred upper limit is usually about 250%.

The technical key points of image forming material which can be applied to the thin film thermal transfer recording system are (1) balancing between high-temperature response and storage
5 stability, (2) securing intimate and full contact between the heat transfer sheet and the receiving sheet, (3) use of heat-resistant organic materials, and (4) securing surface cleanness, as hereinafter described.

(1) Balance between high-temperature response and storage
10 stability

The image forming layer must have a small thickness on the order of submicrons in order to attain high image quality on thin film transfer. However, the layer should contain a pigment in a high concentration enough to give a desired image
15 density, which conflicts with fast thermal response. Besides, thermal response properties also conflict with storage (adhesion) stability. These conflicting problems are settled by development of novel polymers and additives.

(2) Vacuum contact

20 In the thin film transfer technique in pursuit of high resolution, the transfer interface is desirably as smooth as possible. However, such surface smoothness interferes with sufficient vacuum contact. In the present invention, departing from the common knowledge relating to vacuum contact, a
25 relatively large amount of a matting agent having a relatively

small particle size is incorporated into a layer between the substrate and the image forming layer thereby to maintain a moderate uniform gap between the transfer sheet and the receiving sheet. As a result, vacuum contact capabilities are achieved without allowing the matting agent to cause dot missing and without ruining the advantages of the thin film transfer technology.

(3) Heat-resistant organic materials

On irradiation, the light-heat conversion layer which converts laser light energy to heat energy reaches about 700°C, and the image forming layer containing a pigment reaches about 500°C. The inventors have developed a binder resin capable of being applied by organic solvent coating techniques as a material of the light-heat conversion layer. They have also developed a pigment as a colorant of the image forming layer which is more heat-resistant than pigments for printing, safe, and fit for color matching.

(4) Surface cleanness

Dust or debris present between the transfer sheet and the receiving sheet leads to serious image defects in thin film transfer. To keep the image forming elements clean, material management alone is insufficient because dust outside the equipment can enter or dust can occur during sheet cutting operation. It has therefore been necessary to fit the equipment with a dust removing mechanism. The inventors have found a

material with moderate tackiness with which the surface of the image forming elements can be cleaned. They have thus succeeded in dust removal without accompanying productivity reduction by using sheet feed rollers made of this material.

5 The whole system according to the invention will hereinafter be described. The present invention is contemplated to produce a heat transfer image of sharp dots, to re-transfer the transfer image to stock paper (paper actually used in printing), and to achieve recording over a wide area.

10 One of the performance features of the system developed by the inventors is capability of forming sharp dots. The resolution achievable with this system is 2400 dpi or higher, and a transfer image having a resolution according to a desired number of lines per inch (lpi) can be obtained by the system.

15 The individual dots have very sharp edges substantially free from blur or deficiency. Full range of dots from highlights to shadows can be formed clearly. Therefore, the system is capable of outputting high quality dots at the same level of resolution as obtained with an image setter or a CTP setter
20 to give a close approximation to dots and gradation of final printed products.

 A second performance feature of the system is satisfactory cyclic reproducibility (repeatability). Since the image forming layer can be transferred in sharp dots, dots are
25 reproduced in good agreement with a laser beam. Additionally,

because of very small environmental dependency of recording characteristics, the results of repetition are stable in hue and density in a wide range of environmental conditions.

A third performance feature of the system is satisfactory
5 color reproducibility. Since the system employs pigments in the image forming layer, which are used in printing inks, and has satisfactory cyclic reproducibility, highly accurate color management system (CMS) can be realized.

The heat transfer image obtained substantially matches
10 the color hues of final prints, i.e., the hues of SWOP (specifications for web offset publications) colors or Japan-colors and shows the same change in what it looks like with a change of lighting (e.g., a fluorescent lamp and an incandescent lamp) as the final printed product.

15 A fourth performance feature of the system is satisfactory text quality. Owing to the sharp dot shape, the system reproduces fine lines of letters with sharp edges.

The material technology adopted to the laser thermal transfer recording system of the invention is then described.
20 As previously noted, thermal transfer techniques for DDCPs include laser sublimation, laser ablation, and laser melt. The laser sublimation system and the laser ablation system result in blurred dot edges because of sublimation or scattering of a colorant. The laser melt system also fails to create clear
25 dot outlines because the molten colorant flows. The system

according to the invention adopts the thin film thermal transfer system. In order to solve problems associated with the laser thermal transfer systems and to further improve the transfer image quality, the following material techniques have been added
5 to the thin film transfer system.

A first material feature of the system is a sharper dot edge. In thermal transfer recording, laser light is converted to heat in the light-heat conversion layer, the heat is transmitted to the adjoining image forming layer, and the image
10 forming layer adheres to the image receiving layer to conduct recording. In order to make sharp dots, it is required that the heat generated by laser light be transmitted right to the transfer interface without being diffused in the planar direction so that the image forming layer may be cut sharply
15 along the borders between heated areas and non-heated areas. For this purpose, the light-heat conversion layer of the heat transfer sheet should be reduced in thickness, and the dynamic characteristics of the image forming layer should be so controlled.

20 Accordingly, a first technique for accomplishing dot sharpening is thickness reduction of the light-heat conversion layer. As simulated, a light-heat conversion layer is assumed to instantaneously reach about 700°C so that a thin light-heat conversion layer is liable to deformation or destruction. A
25 deformed or destroyed thin light-heat conversion layer would

be transferred to an image receiving sheet together with an image forming layer or result in an uneven transfer image. Beside this problem, a light-heat conversion layer must have a light-heat converting substance in a high concentration so as to reach a prescribed temperature, which can cause additional problems such as colorant's precipitation or migration to an adjacent layer. To address these problems, the heat transfer sheet of the invention employs an infrared absorbing colorant as a light-heat converting substance which is effective at a reduced amount compared with carbon that has been often used as a light-heat converting substance. With respect to a binder, a resin which retains sufficient mechanical strength even at high temperatures and has satisfactory ability to hold an infrared absorbing colorant is selected.

In this way, it is preferred to reduce the light-heat conversion layer thickness to about 0.5 μm or smaller by selecting an infrared absorbing colorant exhibiting excellent light-heat conversion characteristics and a heat-resistant binder such as polyimide or polyamide-imide.

The combined use of the infrared absorbing colorant and the polyamide-imide resin in the light-heat conversion layer produces the following effects. The storage stability of a coating composition for light-heat conversion layer is improved thereby to prevent reduction in absorbance of the light-heat conversion layer that might occur due to storage of the coating

composition. The absorbance of the light-heat conversion layer is increased, which leads to improved sensitivity. Change in hue after irradiation is reduced to improve light fastness of the transferred image.

5 A second technique for dot sharpening is for improving the characteristics of the image forming layer. If the light-heat conversion layer is deformed, or if the image forming layer itself undergoes deformation due to high heat, the image forming layer transferred to the image receiving layer suffers
10 from thickness unevenness in response to the slow scanning pattern of a laser beam. It follows that the transfer image becomes non-uniform, and the apparent transfer density reduces. This tendency becomes conspicuous with a decrease in image forming layer thickness. On the other hand, a thick image
15 forming layer has poor dot sharpness and reduced sensitivity.

 In order to solve these problems, it is preferred to reduce transfer unevenness by adding a low-melting substance, such as a wax, to the image forming layer. Furthermore, part of the binder can be replaced with fine inorganic particles to
20 increase the layer thickness to a proper degree so that the image forming layer may be sharply cut along the heated area/non-heated area borders. As a result, uniform recording can be accomplished without impairing dot sharpness and sensitivity.

25 In general, low-melting substances such as waxes tend

to bleed on the surface of the image forming layer or to crystallize, which can result in impairment of image quality or deterioration of stability of the heat transfer sheet with time. To avert this drawback, it is preferred to select a
5 low-melting substance with a small difference in S_p (solubility parameter) value from the polymer of the image forming layer. Such a substance exhibits improved compatibility with the polymer and is prevented from releasing from the image forming layer. It is also preferred for avoiding crystallization to
10 use an eutectic mixture of low-melting substances having different structures. By these manipulations an image of sharp dots free from unevenness can be obtained.

A second material feature of the system lies in improvement on hue approximation to the final output. The system of the
15 invention has introduced the knowledge about color matching management and stable dispersing technique amassed through the development of a thermal head type color proofer (e.g., First Proof supplied by Fuji Photo Film Co., Ltd.) and also settled the following problem that has arisen in the laser thermal
20 transfer system.

A first technique for achieving improved hue approximation to the final output consists in use of a highly heat-resistant pigment. An image forming layer generally reaches about 500°C in laser thermal transfer recording. Some
25 of traditionally employed pigments decompose at such high

temperatures. This problem is settled by using highly heat-resistant pigments in the image forming layer.

A second technique realizing improved hue approximation to the final output resides in prevention of the infrared
5 absorbing colorant from diffusing. If the infrared absorbing colorant used in the light-heat conversion layer migrates to the image forming layer due to the high recording heat, it follows that the hue of a resultant transfer image differs from what is expected. To prevent this, the light-heat conversion layer
10 is preferably made of the infrared absorbing colorant combined with the above-described binder capable of securely holding the infrared absorbing colorant.

A third material feature of the system is improvement on vacuum holding. The image receiving sheet and the heat
15 transfer sheet are preferably held on a recording drum by vacuum holding. The contact of the two sheets by vacuum holding is of great significance because image transfer relies on control of adhesion between the image receiving layer of the image receiving sheet and the image forming layer of the transfer
20 sheet, and the transfer behavior is very sensitive to the clearance therebetween. An increased gap between the two sheets due to dust or debris results in image defects or transfer unevenness. To prevent such image defects and transfer unevenness, it is preferred to give uniform surface roughness
25 to the heat transfer sheet thereby allowing entrapped air to

escape to make a uniform clearance between the two sheets.

Surface roughness is given to the heat transfer sheet side so that the effect of vacuum contact may be fully enjoyed when two or more color images are overprinted. The heat transfer sheet can be textured by post-treatments such as embossing or addition of a matting agent. Addition of a matting agent is preferred for the sake of process simplification and in view of material stability with time. A matting agent to be added should have a particle size larger than the thickness of a layer to which it is added. Addition of a matting agent directly to the image forming layer would result in missing of dots from the part where the matting agent particles stick out. Therefore, a matting agent of optimum particle size is preferably added to the light-heat conversion layer. As a result, the image forming layer provided thereon has an almost uniform thickness and is capable of transferring a defect-free image to the image receiving sheet.

The systematization of the technique according to the present invention will then be described.

A first feature of the systematization is configuration of the recording apparatus. In order to duly reproduce sharp dots, not only the image forming material but also the recording apparatus should be designed precisely. The recording apparatus which can be used has the same basic configuration as conventional thermal transfer recorders. This

configuration is a so-called heat mode outer drum recording system in which a heat transfer sheet and an image receiving sheet held on a drum are irradiated with a recording head having a plurality of high power lasers. The following embodiments
5 are preferred among others.

Firstly, the recording apparatus is designed to avoid contamination with dust. The image receiving sheet and the heat transfer sheet are supplied by a full-automatic roll supply system so as to avoid contamination with dust or debris that
10 might enter if the recording apparatus is manually loaded with a stack of cut sheets. A loading unit containing rolls of the heat transfer sheets of different colors, one roll for one color, rotates to bring each roll to the position where the unrolled continuous sheet is cut at a prescribed length with a cutter,
15 and the cut sheet is held onto a recording drum.

Secondly, the recording apparatus is designed to bring the image receiving sheet and the heat transfer sheet into intimate contact on the recording drum. The image receiving sheet and the heat transfer sheet are held to the drum by suction
20 (vacuum holding). Mechanical holding fails to bring the two sheets into such intimate contact as obtained by vacuum holding. A large number of suction holes are formed on the recording drum, and the inside of the drum is evacuated with a blower or a vacuum pump thereby to hold the sheets onto the drum. The
25 image receiving sheet is the first to be held by suction, and

the heat transfer sheet is superposed thereon. Therefore, the heat transfer sheet is made larger than the image receiving sheet so as to have extensions over every side of the image receiving sheet. Air between the heat transfer sheet and the
5 image receiving sheet, which greatly influences the image transfer, is sucked from the extension area of the heat transfer sheet extending from the underlying image receiving sheet.

Thirdly, the recording apparatus is designed to allow a plurality of output sheets to be stacked stably on an output
10 tray. In the present invention, the recording apparatus is contemplated to provide output sheets of B2 or larger sizes being stacked on the output tray. When a sheet is outputted and superposed on another sheet that has already been discharged, the two sheets can stick to each other because of the heat
15 stickiness of the image receiving layer. If this happens, the next sheet is not discharged in good order to cause jamming. To prevent this from happening, it is the best to prevent the output sheets from coming into contact with each other. Known means for preventing the contact include (a) a level difference
20 made on the output tray, by which the sheet is placed non-flat, and a gap is created between adjacent sheets, (b) a slot for output exit positioned higher than the output tray so that an output sheet discharged through the slot drops on the output tray, and (c) air ejected between adjacent sheets to float the
25 upper sheet. Since the sheet size is as large as B2, application

of the means (a) or (b) will make the apparatus considerably larger. Therefore, the means (c), i.e., an air ejection method is employed in this system.

Fig. 2 shows a recording apparatus 1 as an example of
5 the recording apparatus which can be used in the invention.

Referring to Fig. 2, steps for full color image formation by use of the image forming material according to the invention and the above-described recording apparatus are illustrated below in sequence.

- 10 1) A recording head 2 which slides on rails 3 in the slow scan (sub-scan) direction, a recording drum 4 which rotates in the fast scan (main scan) direction, and a heat transfer sheet loading unit 5 return to their starting positions.
- 2) An image receiving sheet is unrolled from an image
15 receiving sheet roll 6 with feed rollers 7, and the leading end of the image receiving sheet is fixed by suction onto the recording drum 4 through suction holes of the recording drum.
- 3) A squeegee roller 8 comes down and presses the image receiving sheet to the recording drum 4. In this state, the
20 drum 4 rotates to further unroll the image receiving sheet. When a given length is unrolled, the drum stop rotating, and a cutter 9 cuts the unrolled sheet.
- 4) The recording drum 4 further turns to makes one revolution to complete image receiving sheet loading.
- 25 5) A heat transfer sheet of the first color, e.g., black

(K) , is unrolled from a heat transfer sheet roll 10K, held onto the recording drum 4, and cut into a sheet of prescribed length according to the same sequence as for the image receiving sheet.

6) The recording drum 4 starts to rotate at high speed, and

5 the recording head 2 starts to move on the rails 3. When the recording head 2 arrives at a record starting position, it emits writing laser beams to irradiate the transfer material (heat transfer sheet and the image receiving sheet) held on the recording drum 4 according to recording signals. The irradiation
10 is stopped at a recording terminal position, and the operations of the rails 3 and the drum 4 stop. The recording head 2 on the rails 3 returns to its starting position.

7) Only the heat transfer sheet K is peeled off with the image receiving sheet left on the recording drum. The leading

15 end of the heat transfer sheet K is caught in claws, pulled apart from the image receiving sheet, and discarded through a discard slot 32 into a waste box 35.

8) The steps (5) to (7) are repeated for each of the other heat transfer sheets. Recording is performed in the order of,

20 for example, black (K) , cyan (C) , magenta (M) , yellow (Y) , and other optional colors. That is, for example, a heat transfer sheet of the second color (C) , a heat transfer sheet of the third color (M) , a heat transfer sheet of the fourth color (Y) , and, if desired, a heat transfer sheet of the fifth color (R)
25 are successively fed from rolls 10C, 10M, 10Y, and 10R,

respectively. The order of color superimposition in the recording apparatus is the reverse of the general printing order because the resulting color image is reversed on re-transfer to paper to give a color proof. The order of color
5 superimposition is not particularly limited.

9) After completion of the above steps, the recorded image receiving sheet is discharged on an output tray 31. The image receiving sheet is separated from the recording drum in the same manner as for the heat transfer sheets (as described in
10 step (7)) but is not discarded. When it comes near the discard slot 32, it changes its direction by a switchback mechanism and is forwarded to the output tray. When the image receiving sheet exits through the discharge slot 33, air 34 is blown from
15 under the slot 33 to allow a plurality of sheets to be stacked without sticking to each other.

When image formation is effected on demand, a coating composition for image forming layer is applied to the intermediate layer of a laminate sheet to prepare a heat transfer sheet having an image forming layer of desired hue. Thereafter,
20 an image is formed in accordance with the sequence described above using the thus prepared heat transfer sheet. The on-demand image forming method eliminates the necessity to stock a large volume of heat transfer sheets having the respective image forming layers. This is particularly advantageous where heat
25 transfer sheets of a wide variety of colors are required in

small lots.

Application of the coating composition to an intermediate layer is carried out by blade coating, roll coating, bar coating, curtain coating, gravure coating or like coating techniques.

5 It is preferred to use an adhesive roller as one of paired feed rollers 7 disposed on any site between the recording drum 4 and each of the image receiving sheet roll and the heat transfer sheet roll to clean the surface of the heat transfer sheet and the image receiving sheet.

10 The adhesive roller has a sticky material on its surface. The sticky material includes an ethylene-vinyl acetate copolymer, an ethylene-ethyl acrylate copolymer, a polyolefin resin, a polybutadiene resin, a styrene-butadiene copolymer (SBR), a styrene-ethylene-butene-styrene copolymer (SEBS), an
15 acrylonitrile-butadiene copolymer (NBR), a polyisoprene resin (IR), a styrene-isoprene copolymer (SIS), an acrylic ester copolymer, a polyester resin, a polyurethane resin, an acrylic resin, butyl rubber, and polynorbornene.

20 The surface of the heat transfer sheet and the image receiving sheet can be cleaned on contact with the adhesive roller. The contact pressure is not particular limited.

 It is preferred that the sticky material used in the adhesive roller has a Vickers hardness Hv of 50 kg/mm² (≈490 MPa) or less for thoroughly removing dust and thereby preventing
25 image defects caused by dust. "Vickers hardness" is a hardness

measured by applying a static load to a quadrangular pyramidal diamond indenter having an angle of 136° between the opposite faces. Vickers hardness Hv is obtained from equation:

$$Hv=1.854 P/d^2 \text{ (kg/mm}^2\text{)} \approx 18.1692 P/d^2 \text{ (MPa)}$$

5 where P is a load (kg) applied, and d is the length (mm) of a diagonal of a square indentation.

It is also preferred for the sticky material to have an elastic modulus of 200 kg/cm² (≈19.6 MPa) or less at 20°C for the same purpose as described above.

10 A second feature of the systematization is configuration of a thermal transfer apparatus. A thermal transfer apparatus is used to carry out the step of re-transferring the transfer image on the image receiving sheet to a sheet of the same paper as used in final printing (hereinafter simply referred to as
15 a paper sheet). This step is entirely identical to that carried out in First Proof (a trade mark of a thermal transfer apparatus available from Fuji Photo Film Co., Ltd.). A paper sheet is superposed on the image receiving sheet, and heat and pressure are applied thereto to adhere the two sheets together. Then,
20 the image receiving sheet is stripped off the paper sheet, whereby only the substrate and a cushioning layer (if provided as hereinafter described) of the image receiving sheet are removed to leave the image and the image receiving layer on the paper sheet. This practically means that the image is
25 transferred from the image receiving sheet to the printing paper

sheet.

In First Proof™, image re-transfer is performed by superposing a paper sheet and the image receiving sheet on an aluminum guide plate and passing them through a pair of heat
5 rollers. The aluminum guide plate serves to prevent the paper from deformation. If this design is applied as such to the system for B2 size output, the aluminum guide plate should be larger than a B2 size, which results in the problem that a large installation space is required. Accordingly, the system of
10 the present invention does not use such an aluminum guide plate. Instead, the carrier path turns 180° so that the sheets are discharged toward the loading side. As a result, the installation space can be largely saved (see Fig. 3). However, there arises another problem that the paper sheet is curled
15 in the absence of an aluminum guide plate. The facing couple of the paper sheet and the image receiving sheet curls with the image receiving sheet inward and rolls on the output tray. It is very difficult to separate the image receiving sheet from the curled paper.

20 In the present invention, this curling phenomenon is averted by taking advantage of bimetallic effect due to the difference in shrinkage between printing paper and the image receiving sheet and the ironing effect of the heat roller. Where an image receiving sheet is superposed on a paper sheet as in
25 a conventional way, the two sheets curl with the image receiving

sheet inward by bimetallic effect upon heating because the image receiving sheet shows larger thermal shrinkage in the direction of insertion than printing paper. The direction of curling by the bimetallic effect is the same as the direction of curling
5 by the ironing effect of the heat roller around which the two sheets are wound. As a result, the curling becomes serious by synergism. In contrast, when the paper sheet is superposed on an image receiving sheet, downward curling by the bimetallic effect occurs whereas upward curling is caused by ironing effect
10 so that the curls of opposite directions are offset by each other.

Re-transfer to a printing paper sheet is carried out according to the following sequence. A thermal transfer apparatus 41 which can be used for re-transfer is shown in Fig.

15 3. Unlike the laser recording apparatus, the thermal transfer apparatus 41 is manually operated.

1) To begin with, dials (not shown) are turned to set the temperature of heat rollers 43 (variable between 100° and 110°C) and the transfer speed according to the kind of printing paper
20 sheet 42.

2) An image receiving sheet 20 is put on an insertion table 44 with the image side up, and the dust on the image is removed by an antistatic brush (not shown). A paper sheet 42 from which dust has been removed is superposed thereon. Because the upper
25 paper sheet 42 is larger than the lower image receiving sheet

20, it is difficult to position the paper sheet 42 on the image receiving sheet 20 hidden from the eye. For improving the ease of the positioning work, marks 45 indicating the positions of placement for an image receiving sheet and a paper sheet are made on the insertion table 44. The reason the paper sheet is larger than the image receiving sheet 20 is to prevent image receiving sheet 20 from coming out under the paper sheet 42 and staining heat roller 43.

3) The image receiving sheet and the paper sheet are inserted into an insert port, and a pair of insert rollers 46 rotate to forward them to heat rollers 43.

4) When the leading end of the paper sheet 42 reaches the heat rollers 43, the heat rollers nip the two sheets to start heat transfer. The heat rollers are heat resisting silicone rubber rollers. Pressure and heat are applied simultaneously to the image receiving sheet and the paper sheet to adhere them. A heat-resistant guide sheet 47 is provided by the side of the upper heat roller. The image receiving sheet and the paper sheet are carried upward through between the upper heat roller and the guide sheet 47 while being heated, separated from the upper heat roller by separation claws 48, and guided to an output slot 50 along a pair of guide plates 49.

5) The image receiving sheet and the paper sheet coming out of the output slot 50 is discharged on the insertion table while being adhered. Thereafter, the image receiving sheet

20 is separated from the paper sheet 42 by the hand.

The third feature of the systematization technique resides in the system configuration.

The above-illustrated apparatus are connected to a
5 plate-making system to perform the function as a color proofer.
A color proofing system is required to output a color proof
as an approximation to final prints outputted based on certain
page data. Therefore, software for approximating dots and
colors to the final prints is necessary. A specific example
10 of connection is shown below. Fig. 4 is referred to.

When a proof is to be prepared for the final printing
product outputted from a plate-making system Celebra™ (from
Fuji Photo Film Co., Ltd.), a CTP system is connected to Celebra.
A printing plate outputted from this connection is mounted on
15 a press to carry out actual printing. To Celebra is connected
the above-illustrated thermal transfer recording apparatus as
a color proofer, e.g., Luxel FINALPROOF 5600 from Fuji Photo
Film Co., Ltd. (hereinafter simply referred to as FINALPROOF),
and proof drive software PD SYSTEM™ available from Fuji Photo
20 Film is installed between Celebra and FINALPROOF for
approximating dots and colors to the final output.

Contone data (continuous tone data) converted to raster
data by Celebra are converted to binary data for dots, outputted
to the CTP system, and finally printed. On the other hand,
25 the same contone data are also sent to PD SYSTEM. PD SYSTEM

converts the received data according to a multi-dimensional table for each color so that the colors may agree with the final output. Finally the data are converted to binary data for dots so as to agree with the dots of the final output, which are
5 sent to FINALPROOF.

The multi-dimensional table for each color is experimentally prepared in advance and stored in the system. The experiment for the preparation of the multi-dimensional table is as follows. Data of an important color are outputted
10 via the CTP system to prepare a printed image. The same data are also outputted from FINALPROOF via PD SYSTEM to prepare a proof image. The measured color values of these images are compared, and a table is prepared so as to minimize the difference.

15 Thus, the system configuration is set up so that the performance of the high-resolution image forming material of the invention may be exhibited to the full.

The heat transfer sheet suitably used in the above-described system is then described.

20 It is preferred that the absolute value of the difference in surface roughness R_z (defined later) between the exterior and the interior sides of the image forming layer of the heat transfer sheet be 3.0 μm or smaller and that the absolute value of the difference in surface roughness R_z between the exterior
25 and the interior sides of the image-receiving layer of the image

receiving sheet be 3.0 μm or smaller. Such a layer design combined with the above-described cleaning means prevents image defects and jamming in the sheet path and reduces variations in dot gain.

5 The surface roughness Rz is a 10 point height parameter corresponding to the Rz (maximum height) specified in JIS B 0601. The surface roughness Rz is obtained by computing the average height difference between the five highest peaks and the five lowest valleys with respect to the mean plane within
10 an evaluation area. A stylus type 3D roughness meter (Surfcom 570A-3DF, available from Tokyo Seimitsu Co., Ltd.) is used for measurement. The measurement is performed in the longitudinal direction, the cut-off length is 0.08 mm, the evaluation area is 0.6 mm by 0.4 mm, the sampling pitch is 0.005 mm, and the
15 speed of measurement is 0.12 mm/sec.

For enhancing the above-described effects, it is still preferred that the absolute difference in Rz between the exterior and the interior surfaces of the image forming layer be 1.0 μm or smaller and that the absolute difference in Rz between the
20 exterior and the interior sides of the image receiving layer be 1.0 μm or smaller.

In another layer design, it is preferred that the surface roughness Rz of both the exterior and the interior sides of the image forming layer of the heat transfer sheet and/or both
25 the exterior and the interior sides of the image receiving layer

of the image receiving sheet be in a range of from 2 to 30 μm . Such a surface profile combined with the above-described cleaning means prevents image defects and jamming in the sheet path and reduces variations in dot gain.

5 It is preferred for the image forming layer of the heat transfer sheet to have a surface gloss of 80 to 99. The surface gloss of the image forming layer largely depends on the smoothness of the layer and relates to the thickness uniformity of the layer. An image forming layer with a higher surface
10 gloss has higher thickness uniformity and is more suited for high precision image formation. However, higher smoothness leads to higher resistance in sheet transportation. That is, the smoothness and ease of transportation conflict with each other. Where the surface gloss ranges 80 to 99, a good balance
15 between smoothness and ease of transportation will be achieved.

The scheme of image formation by thin film thermal transfer using a laser is described by referring to Fig. 1.

An image forming laminate 30 composed of a heat transfer sheet 10 and an image receiving sheet 20 is prepared (see Fig.
20 1A). The heat transfer sheet 10 has a substrate 12, a light-heat conversion layer 14 provided on the substrate 12, and an image forming layer 16 containing a pigment (black (K), cyan (C), magenta (M), yellow (Y), etc.) provided on the light-heat conversion layer 14. The image receiving sheet 20 has a
25 substrate 22 and an image receiving layer 24. The two sheets

10 and 20 are superposed with the image receiving layer 24 facing the image forming layer 16. On imagewise irradiating the laminate 30 with a laser beam from the side of the substrate 12 of the heat transfer sheet 10 in a time series, the irradiated area of the light-heat conversion layer 14 of the heat transfer sheet 10 generates heat to reduce its adhesion to the image forming layer 16 (see Fig. 1B). The heat transfer sheet 10 is stripped off the image receiving sheet 20 while leaving the irradiated area 16' of the image forming layer 16 on the image receiving layer 24 of the image receiving sheet 20. That is, the image is transferred (see Fig. 1C).

The laser light for imagewise irradiation is preferably multi-beam light, particularly multibeam of two-dimensional array. Multibeam of two-dimensional array is a plurality of laser beams arranged in a two-dimensional array such that the spots of these laser beams form a plurality of lines in the fast scan direction and a plurality of rows in the slow scan direction. Use of multibeam in a two-dimensional array reduces the time required for laser recording.

Laser beams of any kind can be used in recording with no limitation, including direct laser beams such as gas laser beams, e.g., an argon ion laser beam, a helium neon laser beam, and a helium cadmium laser beam, solid state laser beams, e.g., a YAG laser beam, a semiconductor laser beam, a dye laser beam, and an excimer laser beam. Light rays obtained by converting

these laser beams to half the wavelength through a second harmonic generation device can also be used. In multicolor image formation, semiconductor laser beams are preferably used taking the output power and ease of modulation into consideration.

5 In multicolor image formation, a laser beam is preferably emitted to give a spot diameter of 5 to 50 μm , particularly 6 to 30 μm , on the light-heat conversion layer. The scanning speed is preferably 1 m/sec or higher, still preferably 3 m/sec or higher.

10 In multicolor image formation, the thickness of the black image forming layer in the black heat transfer sheet is preferably larger than that of the other image forming layers of the other heat transfer sheets (e.g., yellow, magenta, cyan, etc.) and preferably ranges from 0.5 to 0.7 μm . This layer
15 thickness design is effective to prevent density reduction due to non-uniform transfer of the black image forming layer. With the thickness being 0.5 μm or greater, the black image forming layer can be uniformly transferred when recorded with high energy thereby attaining a satisfactory image density necessary as
20 a color proof for printing. Since the tendency to transfer unevenness becomes outstanding under high humidity conditions, the thickness of 0.5 μm or greater is particularly effective to reduce environment-induced variations in density. On the other hand, the black image forming layer thickness of 0.7 μm
25 or smaller is effective in maintaining the transfer sensitivity

in laser recording and improving reproducibility of small dots and fine lines. These effects are more conspicuous under low humidity conditions. Resolution can also be improved with the above layer thickness. The layer thickness of the black image forming layer of the black heat transfer sheet is still
5 preferably 0.55 to 0.65 μm , particularly preferably 0.58 to 0.62 μm .

In addition to the black image forming layer thickness ranging 0.5 to 0.7 μm , it is preferred that the thickness of
10 the image forming layers of other heat transfer sheets (e.g., yellow, magenta, cyan, etc.) be from 0.2 to less than 0.5 μm . The 0.2 μm or greater thickness of these image forming layers (e.g., yellow, magenta, cyan, etc.) is effective to prevent transfer unevenness thereby to maintain the image density in
15 laser recording. With the thickness of these color image forming layers being less than 0.5 μm , the transfer sensitivity and resolution are improved. A still preferred thickness of these image forming layers is from 0.3 to 0.45 μm .

The black image forming layer of the black heat transfer
20 sheet preferably contains carbon black. The carbon black to be used preferably comprises at least two kinds different in tinting strength from the viewpoint of ease of controlling reflection density while maintaining a pigment/binder ratio within a specific range.

25 The tinting strength of carbon black can be represented

in various terms. PVC blackness disclosed in JP-A-10-140033 is among them. PVC blackness of carbon black is determined as follows. Carbon black to be evaluated is dispersed in a polyvinyl chloride resin by a two-roll mill and molded into a sheet. The blacknesses of Carbon Black #40 and #45, both available from Mitsubishi Chemicals Co., Ltd. being taken as 1 point and 10 points, respectively, the PVC blackness of the sample sheet is rated by visual observation on a 10 point scale. Two or more carbon blacks having different PVC blacknesses can be used in an appropriate combination according to the purpose.

Preparation of sample:

The following components are kneaded in a 250 cc Banbury mixer at 115°C for 4 minutes to prepare a master batch having a carbon black content of 40% by weight.

Master batch formulation:

Low-density linear polyethylene (LDPE)	101.89 g
Calcium stearate	1.39 g
Irganox 1010	0.87 g
Carbon black	69.43 g

The master batch is diluted according to the following formulation in a two-roll mill at 120°C to prepare a compound having a carbon black content of 1% by weight.

Compound formulation:

LDPE	58.3 g
------	--------

Calcium stearate 0.2 g

Carbon black master batch 1.5 g

The resulting compound is extruded through a slit width of 0.3 mm, and the extruded sheet is cut into chips. The chips
5 are molded into a film having a thickness of $65 \pm 3 \mu\text{m}$ on a hot plate set at 240°C .

In multicolor image formation, images of different colors are successively transferred onto the same image receiving sheet by using heat transfer sheets of different colors to form a
10 multicolor image on the image receiving sheet. Alternatively, the image forming layers of heat transfer sheets of different colors are separately transferred to as many image receiving sheets as the heat transfer sheets, and the transfer images are re-transferred onto a sheet of printing paper, etc. to form
15 a multicolor image on the paper.

More specifically, the latter method of forming a multicolor image is carried out, for example, as follows. A laminate of an image receiving sheet and a heat transfer sheet is prepared for each of four or more colors (cyan, magenta,
20 yellow, black, etc.). Each laminate is irradiated with laser light in accordance with the respective digital signals (e.g., through a color separation filter), and the heat transfer sheet is stripped off the image receiving sheet to obtain a color separated image for each color on the image receiving sheet.
25 Thereafter, the color separated images are successively

re-transferred to an actual support, such as printing paper or an equivalent, to form a multicolor image.

While the aforementioned laser thermal transfer recording technology is preferably applied to thin film thermal transfer recording, it is also applicable to other thermal transfer systems, such as melt transfer recording, ablation transfer recording, and sublimation transfer recording. Therefore, the system of the invention includes in its scope the image forming elements useful in these other thermal transfer recording systems.

The image forming material according to the present invention, including the heat transfer sheet and the image receiving sheet will be described in detail.

The heat transfer sheet essentially comprises a substrate, a light-heat conversion layer, and an image forming layer and optionally has other layers such as an intermediate layer.

The substrate of the heat transfer sheet can be of any material of choice. It is desirable for the substrate to have stiffness, dimensional stability, and heat resistance withstanding the heat of laser recording. Preferred substrate materials include synthetic resins, such as polyethylene terephthalate, polyethylene-2,6-naphthalate, polycarbonate, polymethyl methacrylate, polyethylene, polypropylene, polyvinyl chloride, polyvinylidene chloride, polystyrene, styrene-acrylonitrile copolymers, polyamide (aromatic or

aliphatic), polyimide, polyamide-imide, and polysulfone. A biaxially stretched polyethylene terephthalate film is preferred of them from the standpoint of mechanical strength and dimensional stability against heat. In the preparation of color proofs by laser recording, the substrate of the heat transfer sheet is preferably made of transparent synthetic resins which transmit laser beams. The thickness of the substrate is preferably 25 to 130 μm , still preferably 50 to 120 μm . The substrate preferably has a center-line average surface roughness R_a of less than 0.1 μm on its image forming layer side. In the present invention R_a values are measured in accordance with JIS B0601 with, for example, a profilometer (e.g., Surfcom available from Tokyo Seiki Co., Ltd.). The substrate preferably has a Young's modulus of 200 to 1200 kg/mm^2 (≈ 2 to 12 GPa) in the machine direction (MD) and of 250 to 1600 kg/mm^2 (≈ 2.5 to 16 GPa) in the transverse direction (TD). The F-5 value of the substrate in the MD is preferably 5 to 50 kg/mm^2 (≈ 49 to 490 MPa), and that in the TD is preferably 3 to 30 kg/mm^2 (≈ 29.4 to 294 MPa). The F-5 value in the MD is generally higher than that in the TD, but this is not the case when the substrate is required to be stronger in the TD than in the MD. The thermal shrinkage of the substrate when treated at 100°C for 30 minutes is preferably 3% or less, still preferably 1.5% or less, in both TD and MD. The thermal shrinkage at 80°C for 30 minutes is preferably 1% or less, still preferably 0.5%

or less, in both MD and TD. The substrate preferably has a breaking strength of 5 to 100 kg/mm² (\approx 49 to 980 MPa) in both directions and an elastic modulus (20°C) of 100 to 2,000 kg/mm² (\approx 0.98 to 19.6 GPa).

5 In order to improve adhesion between the substrate and the light-heat conversion layer, the substrate may be subjected to a surface activation treatment and/or be provided with one or more undercoating layers. The surface activation treatment includes glow discharge treatment and corona discharge
10 treatment. The materials of the undercoating layer(s) are preferably selected from those having high adhesion to both the substrate and the light-heat conversion layer, low heat conductivity, and high heat resistance. Such materials include polystyrene, a styrene-butadiene copolymer, and gelatin. The
15 total thickness of the undercoating layers is generally 0.01 to 2 μ m. If desired, the opposite side of the substrate may also be surface-treated or provided with a functional layer, such as an antireflection layer or an antistatic layer. It is particularly advisable to provide a backcoating layer
20 containing an antistatic agent on the back of the substrate.

 The backcoating layer preferably comprises a first backcoating layer contiguous to the substrate and a second backcoating layer provided on the first backcoating layer. It is preferred that the weight ratio of the antistatic agent B
25 contained in the second backcoating layer to the antistatic

agent A contained in the first backing layer, B/A, be less than 0.3. A B/A ratio of 0.3 or more tends to result in reduction of sliding properties and cause powder fall-off from the backcoating layer.

5 The thickness C of the first backcoating layer is preferably 0.01 to 1 μm , still preferably 0.01 to 0.2 μm . The thickness D of the second backcoating layer is preferably 0.01 to 1 μm , still preferably 0.01 to 0.2 μm . The thickness ratio C/D is preferably 1/2 to 5/1.

10 The antistatic agents which can be used in the first and second backcoating layers include nonionic surface active agents, e.g., polyoxyethylene alkylamines and glycerol fatty acid esters; cationic surface active agents, e.g., quaternary ammonium salts; anionic surface active agents, e.g.,
15 alkylphosphates; amphoteric surface active agents; and electrically conductive resins.

 Fine electrically conductive particles can also be used as an antistatic agent. Examples of such fine electrically conductive particles include oxides, e.g., ZnO, TiO₂, SnO₃, Al₂O₃,
20 In₂O₃, MgO, BaO, CoO, CuO, Cu₂O, CaO, SrO, BaO₂, PbO, PbO₂, MnO₂, MoO₃, SiO₂, ZrO₂, Ag₂O, Y₂O₃, Bi₂O₃, Ti₂O₃, Sb₂O₃, Sb₂O₅, K₂Ti₆O₁₃, NaCaP₂O₁₈, and MgB₂O₅; sulfides, e.g., CuS and ZnS; carbides, e.g., SiC, TiC, ZrC, VC, NbC, MoC, and WC; nitrides, e.g., Si₃N₄, TiN, ZrN, VN, NbN, and Cr₂N; borides, e.g., TiB₂, ZrB₂, NbB₂,
25 TaB₂, CrB, MoB, WB, and LaB₅; silicides, e.g., TiSi₂, ZrSi₂,

NbSi₂, TaSi₂, CrSi₂, MoSi₂, and WSi₂; metal salts, e.g., BaCO₃, CaCO₃, SrCO₃, BaSO₄, and CaSO₄; and composites, e.g., SiN₄/SiC and 9Al₂O₃/2B₂O₃. These electrically conductive substances may be used either alone or in a combination of two or more thereof.

5 Preferred of them are SnO₂, ZnO, Al₂O₃, TiO₂, In₂O₃, MgO, BaO, and MoO₃. Still preferred are SnO₂, ZnO, In₂O₃, and TiO₂, with SnO₂ being particularly preferred.

In laser thermal transfer recording, the antistatic agents used in the backcoating layer are preferably
10 substantially transparent so as to transmit laser beams.

In using an electrically conductive metal oxide as the antistatic agent, the particle size is preferably as small as possible to minimize light scattering, but the particle size should be determined based on the ratio of the refractive index
15 of the particles to that of the binder as a parameter, which can be obtained according to Mie theory. The average particle size of the electrically conductive metal oxide is generally 0.001 to 0.5 μm, preferably 0.003 to 0.2 μm. The term "average particle size" as used herein is intended to cover not only
20 primary particles but agglomerates.

The first and second backcoating layers may further contain a binder and various other additives, such as surface active agents, slip agents, and matting agents. The amount of the antistatic agent in the first backcoating layer is
25 preferably 10 to 1,000 parts by weight, still preferably 200

to 800 parts by weight, per 100 parts by weight of the binder. The amount of the antistatic agent in the second backcoating layer is preferably 0 to 300 parts by weight, still preferably 0 to 100 parts by weight, per 100 parts by weight of the binder.

5 The binders which can be used in the first and second backcoating layers include homopolymers and copolymers of acrylic monomers, e.g., acrylic acid, methacrylic acid, acrylic esters and methacrylic esters; cellulosic polymers, e.g., nitrocellulose, methyl cellulose, ethyl cellulose, and
10 cellulose acetate; polymers of vinyl compounds, e.g., polyethylene, polypropylene, polystyrene, vinyl chloride copolymers, vinyl chloride-vinyl acetate copolymers, polyvinyl pyrrolidone, polyvinyl butyral, and polyvinyl alcohol; condensed polymers, e.g., polyester, polyurethane, and
15 polyamide; elastic thermoplastic polymers, e.g., butadiene-styrene copolymers; polymers obtained by polymerization or crosslinking of photopolymerizable or heat polymerizable compounds, e.g., epoxy compounds; and melamine compounds.

20 The light-heat conversion layer comprises a light-heat converting substance and a binder. If necessary, it can contain a matting agent. It may further contain other additives, if desired.

25 The light-heat converting substance is a substance capable of converting light energy to heat energy when irradiated

with light. This substance is generally a colorant (inclusive of a dye and a pigment) capable of absorbing laser light. In infrared laser recording, infrared absorbing colorants are preferably used. Useful infrared absorbing colorants include
5 black pigments, e.g., carbon black; macrocyclic compound pigments showing absorption in the visible to near-infrared region, such as phthalocyanine pigments and naphthalocyanine pigments; organic dyes used in high-density laser recording media (e.g., optical disks), such as cyanine dyes (e.g.,
10 indolenine dyes), anthraquinone dyes, azulene dyes, and phthalocyanine dyes; and organometallic colorants, such as dithiol nickel complexes. *Inter alia*, cyanine dyes have a high absorptivity coefficient in the infrared region. Use of the cyanine dyes as a light-heat converting substance makes it
15 feasible to reduce the thickness of the light-heat conversion layer, which leads to improved recording sensitivity of the heat transfer sheet. Useful light-heat converting substances include not only the colorants but inorganic materials such as particulate metallic materials, e.g., blackened silver.

20 The binder which can be used in the light-heat conversion layer is preferably a resin having strength enough to form a layer on the substrate and a high heat conductivity, still preferably a resin having such heat resistance so as not to decompose by the heat generated by the light-heat converting
25 substance. A heat-resistant resin maintains the surface

smoothness of the light-heat conversion layer after irradiation with high energy light. Specifically, the binder resin preferably has a decomposition temperature at 50% weight loss (T_{d50}) of 370°C or higher in thermogravimetric analysis (TGA) at a rate of temperature rise of 10°C/min in an air stream. The binder resin still preferably has a decomposition temperature at 5% weight loss (T_{d5}) of 400°C or higher, particularly 500°C or higher, in TGA under the same conditions. The binder resin preferably has a glass transition temperature (T_g) of 200° to 400°C, particularly 250° to 350°C. Resins having a T_g lower than 200°C can cause fogging. Resins having a T_g higher than 400°C have reduced solubility in a solvent, which can result in reduction of productivity.

It is preferred for the binder of the light-heat conversion layer to have higher heat resistance (e.g., heat deformation temperature and heat decomposition temperature) than the materials used in other layers provided on the light-heat conversion layer.

Useful binder resins for the light-heat conversion layer include acrylic resins, e.g., polymethyl methacrylate; polycarbonate; vinyl resins, e.g., polystyrene, vinyl chloride-vinyl acetate copolymers, and polyvinyl alcohol; polyvinyl butyral, polyester, polyvinyl chloride, polyamide, polyimide, polyamide-imide, polyether imide, polysulfone, polyether sulfone, aramid, polyurethane, epoxy resins, and

urea-melamine resins. These binder resins can be used individually or as a combination thereof. Polyamide-imide resins and polyimide resins are especially preferred of them.

Particularly preferred polyamide-imide resins are
5 represented by formula (A):

wherein R represents a divalent linking group.

Examples of suitable linking groups R are shown below.

(14)

(15)

(16)

(17)

(18)

(19)

(20)

(21)

(22)

(23)

Preferred of these linking groups are (6), (7), (11), and (14). Combinations of the linking groups illustrated above are also useful.

The above-described polyamide-imide resins preferably have a polystyrene equivalent weight average molecular weight of 3,000 to 50,000, particularly 10,000 to 25,000, measured by gel-permeation chromatography.

Particularly preferred polyimide resins are represented by formulae (I) to (VII) shown below.

In formulae (I) and (II), Ar^1 represents an aromatic group represented by structural formulae (1) to (3); and n represents an integer of 10 to 100.

In formulae (III) and (IV), Ar^2 represents an aromatic group represented by structural formulae (4) to (7); and n represents an integer of 10 to 100.

In formulae (V) to (VII), n and m each represent an integer of 10 to 100. In formula (VI), the ratio n/m is 6/4 to 9/1.

It is preferred for the binder of the light-heat conversion layer to be soluble in an organic solvent. A binder having a solubility of at least 10 parts by weight per 100 parts by weight of N-methylpyrrolidone at 25°C is deemed organic solvent soluble. A binder having a solubility of 100 parts by weight or more per 100 parts by weight of N-methylpyrrolidone is still preferred.

It is preferred for the binder resin, such as polyamide-imide, used in the light-heat conversion layer to have an S_p (solubility parameter) of 25 or greater as calculated according to Okitsu method (see *Journal of the Adhesion Society of Japan*, Vol. 29, No. 5, 1993). By using a binder resin having an S_p of 25 or greater, migration of the light-heat converting

substance, such as the infrared absorbing colorant, or its decomposition products into the image forming layer is reduced to provide a transfer image with a satisfactory and stable hue.

Of the above-described light-heat converting substances particularly preferred are cyanine dyes having a sulfonic acid group represented by formula (B) shown below in view of their high heat resistance and stability against decomposition with time in a coating composition, i.e., stability against reduction in absorbance. The compounds of formula (B) are especially effective when combined with the polyamide-imide resins as previously stated.

wherein Z represents an atomic group necessary to form a benzene ring, a naphthalene ring, a pyridine ring, a quinoline ring, a pyrazine ring, a quinoxaline ring, etc.; T represents -O-, -S-, -Se-, -N(R¹)-, -C(R²)(R³)- or -C(R⁴)=C(R⁵)-; R¹, R², R³, R⁴, and R⁵ each preferably represent a substituted or unsubstituted alkyl group, a substituted or unsubstituted aryl group or a substituted or unsubstituted alkenyl group; L represents a trivalent linking group made of conjugated 5 or 7 methine groups; M represents a divalent linking group; and X⁺ represents a cation.

The atomic group Z may have one or more substituents R⁶.

The substituents R^6 include an alkyl group, an aryl group, a heterocyclic group, a halogen atom, an alkoxy group, an aryloxy group, an alkylthio group, an arylthio group, an alkylcarbonyl group, an arylcarbonyl group, an alkyloxycarbonyl group, an aryloxycarbonyl group, an alkylcarbonyloxy group, an arylcarbonyloxy group, an alkylamido group, an arylamido group, an alkylcarbamoyle group, an arylcarbamoyle group, an alkylamino group, an arylamino group, a carboxyl group, an alkylsulfonyl group, an arylsulfonyl group, an alkylsulfonamido group, an arylsulfonamido group, an alkylsulfamoyl group, an arylsulfamoyl group, a cyano group, and a nitro group. The number of the substituents R^6 that are possessed by Z is usually up to about 4. Where there are two or more substituents R^6 , they may be the same or different.

Preferred substituents R^6 include a halogen atom (e.g., F or Cl), a cyano group, a substituted or unsubstituted alkoxy group having 1 to 20 carbon atoms (e.g., methoxy, ethoxy, dodecyloxy or methoxyethoxy), a substituted or unsubstituted phenoxy group having 6 to 20 carbon atoms (e.g., phenoxy, 3,5-dichlorophenoxy or 2,4-di-t-pentylphenoxy), a substituted or unsubstituted alkyl group having 1 to 20 carbon atoms (e.g., methyl, ethyl, isobutyl, t-pentyl, octadecyl or cyclohexyl), and a substituted or unsubstituted phenyl group having 6 to 20 carbon atoms (e.g., phenyl, 4-methylphenyl, 4-trifluoromethylphenyl or 3,5-dichlorophenyl).

In T representing $-O-$, $-S-$, $-Se-$, $-N(R^1)-$, $-C(R^2)(R^3)-$ or $-C(R^4)=C(R^5)-$, R^1 , R^2 , R^3 , R^4 , and R^5 each still preferably represent an alkyl group. The group represented by R^1 , R^2 , R^3 , R^4 or R^5 preferably contains 1 to 30 carbon atoms, particularly
5 1 to 20 carbon atoms.

Substituents the groups R^1 , R^2 , R^3 , R^4 , and R^5 may have preferably include a sulfonic acid group, an alkylcarbonyloxy group, an alkylamido group, an alkylsulfonamido group, an alkoxy carbonyl group, an alkylamino group, an alkylcarbamoyl
10 group, an alkylsulfamoyl group, an alkoxy group, an aryloxy group, an alkylthio group, an arylthio group, an alkyl group, an aryl group, a carboxyl group, a halogen atom, and a cyano group.

Still preferred among these substituents are a halogen
15 atom (e.g., F or Cl), a cyano group, a substituted or unsubstituted alkoxy group having 1 to 20 carbon atoms (e.g., methoxy, ethoxy, dodecyloxy or methoxyethoxy), a substituted or unsubstituted phenoxy group having 6 to 20 carbon atoms (e.g., phenoxy, 3,5-di-chlorophenoxy or 2,4-di-t-pentylphenoxy), a
20 substituted or unsubstituted alkyl group having 1 to 20 carbon atoms (e.g., methyl, ethyl, isobutyl, t-pentyl, octadecyl or cyclohexyl), and a substituted or unsubstituted phenyl group having 6 to 20 carbon atoms (e.g., phenyl, 4-methylphenyl, 4-trifluoromethylphenyl or 3,5-dichlorophenyl). R^1 , R^2 , R^3 ,
25 R^4 , and R^5 each particularly preferably represent an

5

5

wherein Y represents a hydrogen atom or a substituent; and R⁷ and R⁸ each represent a hydrogen atom or a substituent; i represents 1 or 2; and j represents 0 or 1.

Particularly preferred linking groups are those providing
5 tricarbo-cyanine dyes, i.e., (L-2), (L-3), (L-4), (L-5), and (L-6). In the linking groups (L-1) to (L-6) illustrated above, suitable substituents as represented by Y include a lower alkyl group (e.g., methyl), a lower alkoxy group (e.g., methoxy), a substituted amino group (e.g., dimethylamino, diphenylamino,
10 methylphenylamino, morpholino, imidazolidinyl or ethoxycarbonylpiperazinyl), an alkylcarbonyloxy group (e.g., acetoxy), an alkylthio group (e.g., methylthio), a cyano group, a nitro group, and a halogen atom (e.g., Br, Cl or F).

Y is preferably a hydrogen atom. R⁷ and R⁸ each preferably
15 represent a hydrogen atom or a lower alkyl group having 1 to 5 carbon atoms (e.g., methyl).

The divalent linking group represented by M is preferably a substituted or unsubstituted alkylene group having 1 to 20 carbon atoms, e.g., ethylene, propylene or butylene.

20 The cation as represented by X⁺ includes a metal ion (e.g., Na⁺ or K⁺), an ammonium ion (e.g., HN⁺(C₂H₅)₃), and a pyridinium ion.

Specific examples of the compounds represented by formula (B) are shown below for illustrative purposes only but not for
25 limitation.

(I'-19)

The compounds of formula (B) are generally synthesized with ease in the same manner as for other carbocyanine dyes by reacting a heterocyclic enamine with an acetal (e.g., $\text{CH}_3\text{O}-\text{CH}=\text{CH}-\text{CH}=\text{CH}-\text{CH}(\text{OCH}_3)_2$), a compound represented by
5 $\text{PhN}-\text{CH}-(\text{CH}-\text{CH})-\text{NHPh}$ (where Ph represents phenyl), etc. For the detail, JP-A-5-116450 can be referred to.

It is preferred that the light-heat converting substance has a decomposition temperature of 200°C or higher, particularly 250°C or higher. A high decomposition temperature eliminates
10 fogging caused by coloring with decomposition products. Light-heat converting substances whose decomposition temperature is lower than 200°C can decompose, and the resultant decomposition products can cause coloring (fogging) to reduce the image quality.

15 While it is desirable that the light-heat conversion layer contain the compound of formula (B) as a main light-heat converting substance, known light-heat converting substances may be used in combination in an amount that does not impair the advantages of the compound of formula (B). The known
20 light-heat converting substances are generally colorants (inclusive of dyes and pigments) capable of absorbing laser light. Such colorants include black pigments, e.g., carbon black; macrocyclic compound pigments showing absorption in the visible to near-infrared region, such as phthalocyanine
25 pigments and naphthalocyanine pigments; organic dyes used in

high-density laser recording media (e.g., optical disks), such as cyanine dyes other than the indolenine dyes of formula (B), anthraquinone dyes, azulene dyes, and phthalocyanine dyes; and organometallic colorants, such as dithiol nickel complexes.

5 The matting agents which can be added to the light-heat conversion layer include fine inorganic or organic particles. The fine inorganic particles include metal oxides, e.g., silica, titanium oxide, aluminum oxide, zinc oxide, and magnesium oxide, metal salts, e.g., barium sulfate, magnesium sulfate, aluminum
10 hydroxide, magnesium hydroxide, and boron nitride, kaolin, clay, talc, zinc flower, lead white, zeeklite, quartz, diatomaceous earth, pearlite, bentonite, mica, and synthetic mica. The fine organic particles include particles of fluorine resins, guanamine resins, acrylic resins, styrene-acrylic copolymer
15 resins, silicone resins, melamine resins, and epoxy resins.

The matting agent usually has a particle size of 0.3 to 30 μm , preferably 0.5 to 20 μm . It is preferably added in an amount of 0.1 to 100 mg/m^2 .

If desired, the light-heat conversion layer can contain
20 surface active agents, thickeners, antistatic agents, and the like.

The light-heat conversion layer is formed by applying a coating composition to a substrate and drying the coating. The coating composition is prepared by dissolving the light-heat
25 converting substance and a binder in an organic solvent and

adding thereto a matting agent and other necessary additives. Organic solvents which can be used to dissolve the binder include n-hexane, cyclohexane, diglyme, xylene, toluene, ethyl acetate, tetrahydrofuran, methyl ethyl ketone, acetone, cyclohexanone,
5 1,4-dioxane, 1,3-dioxane, dimethyl acetate, N-methyl-2-pyrrolidone, dimethyl sulfoxide, dimethylformamide, dimethylacetamide, γ -butyrolactone, ethanol, and methanol. Application and drying of the coating composition can be carried out in a conventional manner. Drying
10 is usually effected at temperatures of 300°C or lower, preferably 200°C or lower. Where a polyethylene terephthalate substrate is used, drying is preferably performed at 80 to 150°C.

Where the amount of the binder in the light-heat conversion layer is too small, the light-heat conversion layer has reduced
15 cohesion and tends to accompany the image forming layer being transferred to the image receiving sheet, which causes image color mixing. Use of too much amount of the binder necessitates an increase in layer thickness for achieving a given absorbance, which can invite sensitivity reduction. The solid basis weight
20 ratio of the light-heat converting substance to the binder in the light-heat conversion layer is preferably 1:20 to 2:1, still preferably 1:10 to 2:1.

As the light-heat conversion layer is made thinner, the sensitivity increases as stated previously. The thickness of
25 the light-heat conversion layer is preferably 0.03 to 1.0 μm ,

still preferably 0.05 to 0.5 μm . From the standpoint of transfer sensitivity, the optical density of the light-heat conversion layer is preferably 0.80 to 1.26, still preferably 0.92 to 1.15, at a wavelength of 808 nm. If the optical density at a laser peak wavelength is less than 0.80, light to heat conversion tends to be insufficient, resulting in reduced transfer sensitivity. An optical density exceeding 1.26 will adversely affect the recording function of the light-heat conversion layer, which can result in fogging.

10 The image forming layer of the heat transfer sheet contains a pigment which is transferred to the image receiving sheet to form an image, a binder for forming the layer, and, if desired, other components.

15 The pigment that can be used in the image forming layer are roughly divided into organic ones and inorganic ones. Organic pigments are particularly excellent in film transparency, and inorganic ones are generally excellent in hiding powder. Proper pigments are selected according to the purpose with these characteristics taken into consideration.

20 In making heat transfer sheets for color proofing, it is preferred to use organic pigments whose color tones match or approximate the colors of printing inks, such as yellow (Y), magenta (M), cyan (C), and black (K). Metallic powders, fluorescent pigments, and the like are also used in some cases.

25 Suitable organic pigments include azo pigments, phthalocyanine

pigments, anthraquinone pigments, dioxazine pigments, quinacridone pigments, isoindolinone pigments, and nitro pigments. The pigments useful in the image forming layer are listed below for illustrative purposes only but not for
5 limitation.

1) Yellow pigment

Pigment Yellow 12 (C.I. No. 21090):

Example: Permanent Yellow DHG (from Clariant (Japan) KK),
Lionol Yellow 1212B (from Toyo Ink Mfg. Co., Ltd.),
10 Irgalite Yellow LCT (from Ciba Specialty Chemicals),
Symuler Fast Yellow GTF 219 (from Dainippon Ink & Chemicals,
Inc.)

Pigment Yellow 13 (C.I. No. 21100):

Example: Permanent Yellow GR (from Clariant (Japan) KK),
15 Lionol Yellow 1313 (from Toyo Ink Mfg. Co., Ltd.)

Pigment Yellow 14 (C.I. No. 21095):

Example: Permanent Yellow G (from Clariant (Japan) KK),
Lionol Yellow 1401-G (from Toyo Ink Mfg. Co., Ltd.), Seika
Fast Yellow 2270 (from Dainichiseika Colour & Chemicals
20 Mfg. Co., Ltd.), Symuler Fast Yellow 4400 (from Dainippon
Ink & Chemicals, Inc.)

Pigment Yellow 17 (C.I. No. 21105):

Example: Permanent Yellow GG02 (from Clariant (Japan)
KK), Symuler Fast Yellow 8GF (from Dainippon Ink &
25 Chemicals, Inc.)

Pigment Yellow 155:

Example: Graphtol Yellow 3GP (from Clariant (Japan) KK)

Pigment Yellow 180 (C.I. No. 21290):

Example: Novoperm Yellow P-HG (from Clariant (Japan) KK.) ,

5 PV Fast Yellow HG (from Clariant (Japan) KK.)

Pigment Yellow 139 (C.I. No. 56298):

Example: Novoperm Yellow M2R 70 (from Clariant (Japan)
KK.)

2) Magenta Pigment

10 Pigment Red 57:1 (C.I. No. 15850:1):

Example: Graphtol Rubine L6B (from Clariant (Japan) KK) ,
Lionol Red 6B-4290G (from Toyo Ink Mfg. Co., Ltd.) ,
Irgalite Rubine 4BL (from Ciba Specialty Chemicals) ,
Symuler Brilliant Carmine 6B-229 (from Dainippon Ink &
15 Chemicals, Inc.)

Pigment Red 122 (C.I. No. 73915):

Example: Hosterperm Pink E (from Clariant (Japan) KK.) ,
Lionogen Magenta 5790 (from Toyo Ink Mfg. Co., Ltd.) ,
Fastogen Super Magenta RH (from Dainippon Ink & Chemicals,
20 Inc.)

Pigment Red 53:1 (C.I. No. 15585:1):

Example: Permanent Lake Red LCY (from Clariant (Japan)
KK) , Symuler Lake Red C conc (from Dainippon Ink & Chemicals,
Inc.)

25 Pigment Red 48:2 (C.I. No. 15865:2):

Example: Permanent Red W2T (from Clariant (Japan) KK),
Lionol Red LX235 (from Toyo Ink Mfg. Co., Ltd.), Symuler
Red 3012 (from Dainippon Ink & Chemicals, Inc.)

Pigment Red 177 (C.I. No. 65300):

5 Example: Cromophtal Red A2B (from Ciba Specialty
 Chemicals)

3) Cyan Pigment

Pigment Blue 15 (C.I. No. 74160):

 Example: Lionol Blue 7027 (from Toyo Ink Mfg. Co., Ltd.),
10 Fastogen Blue BB (from Dainippon Ink & Chemicals, Inc.)

Pigment Blue 15:1 (C.I. No. 74160):

 Example: Hosterperm Blue A2R (from Clariant (Japan) KK),
 Fastogen Blue 5050 (from Dainippon Ink & Chemicals, Inc.)

Pigment Blue 15:2 (C.I. No. 74160):

15 Example: Hosterperm Blue AFL (from Clariant (Japan) KK),
 Irgalite Blue BSP (from Ciba Specialty Chemicals),
 Fastogen Blue GP (from Dainippon Ink & Chemicals, Inc.)

Pigment Blue 15:3 (C.I. No. 74160):

 Example: Hosterperm Blue B2G (from Clariant (Japan) KK.),
20 Lionol Blue FG7330 (from Toyo Ink Mfg. Co., Ltd.),
 Cromophtal Blue 4GNP (from Ciba Specialty Chemicals),
 Fastogen Blue FGF (from Dainippon Ink & Chemicals, Inc.)

Pigment Blue 15:4 (C.I. No. 74160):

 Example: Hosterperm Blue BFL (from Clariant (Japan) KK),
25 Cyanine Blue 700-10FG (from Toyo Ink Mfg. Co., Ltd.),

Irgalite Blue GLNF (from Ciba Specialty Chemicals),
Fastogen Blue FGS (from Dainippon Ink & Chemicals, Inc.)

4) Black Pigment

Pigment Black 7 (carbon black C.I. No. 77266):

5 Example: Mitsubishi Carbon Black MA100 (from Mitsubishi
Chemicals Co., Ltd.), Mitsubishi Carbon Black #5 (from
Mitsubishi Chemicals Co., Ltd.), Black Pearls 430 (from
Cabot Co.)

10 The pigments to be used in the invention can be chosen
from commercially available products by referring to Nippon
Ganryo Gijutsu Kyokai (ed.), *Ganryo Binran*, Seibundo Shinko-Sha
(1989), and *COLOUR INDEX, THE SOCIETY OF DYES & COLOURIST*, 3rd
Ed. (1987).

15 The above-described pigments preferably have an average
particle size of 0.03 to 1 μm , particularly 0.05 to 0.5 μm .
Where the average particle size is smaller than 0.03 μm , pigment
dispersing cost tends to increase, and the dispersion tends
to gel. As far as the average particle size is 1 μm or smaller,
there is no coarse particles, which assures good adhesion between
20 the image forming layer and the image receiving layer and
improves the transparency of the image forming layer.

25 The binder to be used in the image forming layer comprises
at least one of the above-specified acrylic resin and
styrene-acrylic copolymer resin both having a Tg of 50°C or
lower and an MFT of 50°C or lower.

The image forming layer can further contain surface active agents, organic or inorganic particles (e.g., metal powder and silicagel), oils (e.g., linseed oil and mineral oil), thickeners, antistatic agents, and so forth. A substance having an absorption at a writing laser wavelength can be added to the image forming layer except for the case where a black image is to be formed, which is beneficial for transfer energy saving. While such a substance may be either a pigment or a dye, it is desirable for color reproduction to use an infrared light source (e.g., semiconductor laser) for writing and to add a dye having a small absorption in the visible region and a large absorption at the wavelength of the light source. Useful near infrared absorbing dyes are described in JP-A-3-103476.

An intermediate layer can be provided on the light-heat conversion layer. The intermediate layer includes a heat-sensitive release layer containing a heat-sensitive material which generates gas or releases adsorption water by the action of the heat generated by the light-heat conversion layer and thereby reduces the adhesive strength between the light-heat conversion layer and the image forming layer. Such a heat-sensitive material includes those compounds, inclusive of polymers and low-molecular compounds, which decompose or denature by heat to generate gas, and those compounds, inclusive of polymers and low-molecular compounds, which have absorbed or adsorbed a considerable amount of a volatile compound, such

as water. These types of compounds may be used in combination.

Polymers which generate gas on thermal decomposition or denaturation include self-oxidizing polymers, e.g., nitrocellulose; halogen-containing polymers, e.g.,
5 chlorinated polyolefin, chlorinated rubber, polychlorinated rubber, polyvinyl chloride, and polyvinylidene chloride; acrylic polymers (e.g., polyisobutyl methacrylate) having adsorbed a volatile compound such as water; cellulose esters (e.g., ethyl cellulose) having adsorbed a volatile compound
10 such as water; and natural high molecular compounds (e.g., gelatin) having adsorbed a volatile compound such as water. Low-molecular compounds which generate gas on heat decomposition or denaturation include those which thermally decompose to generate gas, such as diazo compounds and azide
15 compounds.

It is desirable that decomposition or denaturation of the heat-sensitive material should occur at 280°C or lower, particularly 230°C or lower.

When a low-molecular heat-sensitive material is used in
20 the heat-sensitive release layer, it is preferably used in combination with a binder. The binder to be used may be either of the type that decomposes or denatures to generate gas or of the type that does not. The weight ratio of the low-molecular heat-sensitive material to the binder if used is preferably
25 0.02/1 to 3/1, still preferably 0.05/1 to 2/1. It is preferred

that the heat-sensitive release layer be provided on substantially the entire surface of the light-heat conversion layer. The thickness of the heat-sensitive release layer is usually 0.03 to 1 μm , preferably 0.05 to 0.5 μm .

5 It is preferred to provide a single or multi-layered trapping layer as an intermediate layer on the light-heat conversion layer. A trapping layer traps decomposition products of an infrared absorbing dye produced by the heat of laser recording thereby to prevent or control migration of the
10 decomposition products into the image forming layer. To perform the function, it is preferred for the trapping layer to be compatible with the infrared absorbing dye decomposition products and the light-heat conversion layer. The binder of the trapping layer preferably includes mordant resins, water
15 soluble resins, and resins having an Sp value of 23 or more.

The mordant resins are preferably mordant polymers having a carboxyl group, a sulfo group or a quaternary ammonium salt group in the side chain thereof. The water-soluble resins preferably include polyvinylpyrrolidone, polyvinyl alcohol,
20 gelatin species, water-soluble nylon, cellulosic resins, and modified cellulosic resins. These resins can be used individually or as a combination thereof.

In order for the trapping layer to perform its trapping function without impairing recording sensitivity, the total
25 thickness of the trapping layer is preferably 0.03 to 0.5 μm ,

still preferably 0.03 to 0.1 μm .

It is preferred for the heat transfer sheet to have a coefficient of static friction of 0.35 or smaller, particularly 0.20 or smaller, on its surface of the image forming layer side.

5 With this surface condition, the feed rollers for carrying the heat transfer sheets are prevented from being contaminated, and the quality of the transfer image can be improved. The coefficient of static friction is measured in accordance with the method taught in JP-A-2001-47753, par. [0011].

10 The surface of the image forming layer preferably has a smoother value of 0.5 to 50 mmHg (≈ 0.0665 to 6.65 kPa) at 23°C and 55% RH and a center-line average surface roughness R_a of 0.05 to 0.4 μm . The R_a is measured with a profilometer, e.g., Surfcom (available from Tokyo Seimitsu Co., Ltd.) in
15 accordance with JIS B0601. With these surface roughness parameters falling within the respective ranges, the microscopic spaces formed between the image receiving layer and the image forming layer are reduced in size and number, which favors to image transfer and image quality. The surface
20 hardness of the image forming layer is preferably 10 g or more measured with a sapphire stylus. The static dissipation capability of the image forming layer is preferably such that, when a heat transfer sheet is electrically charged and then grounded according to Federal Test Standard Method 4046, the
25 electrification potential 1 second after grounding is -100 to

100 V. It is preferred that the surface resistivity of the image forming layer at 23°C and 55% RH be $10^9 \Omega$ or less.

The image receiving sheet which can be used in combination with the transfer sheet of the present invention generally comprises a substrate and at least one image receiving layer. The image receiving sheet may additionally have one or more layers selected from a cushioning layer, a release layer, and an intermediate layer provided between the substrate and the image receiving layer. To secure smooth pass of the image receiving sheet in the recording apparatus, it is preferred to provide a backcoating layer on the back side of the substrate.

The substrate of the image receiving sheet includes a resin sheet, a metal sheet, a glass sheet, resin-coated paper, paper, and various composite laminates. Resins which can be used as a substrate include polyethylene terephthalate, polycarbonate, polyethylene, polyvinyl chloride, polyvinylidene chloride, polystyrene, styrene-acrylonitrile copolymers, and polyester. Paper as a substrate includes actual printing paper and coated paper.

It is preferred for the substrate to have micro voids to improve quality of a transfer image. Substrates with micro voids can be obtained by, for example, extruding one or more molten mixtures of a thermoplastic resin and a filler, such as an inorganic pigment or a polymer incompatible with the thermoplastic resin matrix, into a single-layer or multilayer

film and stretching the extruded film uniaxially or biaxially. The void of the resulting stretched film depends on the kinds of the resin and the filler, the mixing ratio, and the stretching conditions.

5 As a thermoplastic resin matrix, a polyolefin resin, such as polypropylene, or polyethylene terephthalate is preferably used in view of their good crystallinity and stretchability necessary to form voids. A combination of a polyolefin resin or polyethylene terephthalate and a minor proportion of other
10 thermoplastic resin is preferred. The inorganic pigment used as a filler preferably has an average particle size of from 1 to 20 μm . Useful pigments are calcium carbonate, clay, diatomaceous earth, titanium oxide, aluminum hydroxide, and silica. In using polypropylene as a thermoplastic resin matrix,
15 polyethylene terephthalate is a preferred filler incompatible with the matrix. For the details of preparation of a substrate with micro voids, reference can be made in JP-A-2001-105752. The content of the filler, such as an inorganic pigment, in the substrate is usually about 2 to 30% by volume.

20 The thickness of the substrate of the image receiving sheet is usually from 10 to 400 μm , preferably 25 to 200 μm . The substrate may be subjected to surface treatment, e.g., corona discharge treatment or glow discharge treatment to have improved adhesion to the image receiving layer (or a cushioning layer
25 if provided as described *infra*) or to improve the adhesion

between the image receiving layer and the image forming layer of the heat transfer sheet.

The image receiving sheet has at least one image receiving layer for receiving and holding the image forming layer being transferred from the heat transfer sheet. The image receiving layer is preferably formed of a resin binder matrix. The resin binder is preferably a thermoplastic resin. Examples of suitable thermoplastic resin binders include homopolymers and copolymers of acrylic monomers, e.g., acrylic acid, methacrylic acid, acrylic esters, and methacrylic esters; cellulosic resins, e.g., methyl cellulose, ethyl cellulose, and cellulose acetate; homopolymers and copolymers of vinyl monomers, e.g., polystyrene, polyvinylpyrrolidone, polyvinyl butyral, polyvinyl alcohol, and polyvinyl chloride; condensed polymers, e.g., polyester and polyamide; and rubbery polymers, e.g., butadiene-styrene copolymers. The binder of the image receiving layer preferably has a T_g of 90°C or lower so as to exhibit moderate adhesion to the image forming layer. A plasticizer may be added to the image receiving layer for the purpose of lowering the T_g . The binder resin preferably has a T_g of 30°C or higher for preventing film blocking. It is particularly preferred that the binder resin of the image receiving layer of the image receiving sheet and that of the image forming layer of the heat transfer sheet be the same or at least analogous to each other so that these layers may be

in intimate contact during laser writing thereby to improve transfer sensitivity and image strength.

The surface of the image receiving layer preferably has a smoother value of 0.5 to 50 mmHg (≈ 0.0665 to 6.65 kPa) measured at 23°C and 55% RH and an Ra of 0.05 to 0.4 μm . The Ra is measured with a profilometer (Surfcom available from Tokyo Seimitsu Co., Ltd.) in accordance with JIS B0601. The surface roughness parameters of the image receiving layer falling within these ranges, the microscopic spaces formed between the image receiving layer and the image forming layer are reduced in size and number, which favors to image transfer and image quality. The static dissipation capability of the image receiving layer is preferably -100 to 100 V as measured in the same manner as described above. It is preferred that the surface resistivity of the image receiving layer at 23°C and 55% RH be $10^9 \Omega$ or less. The image receiving layer preferably has a coefficient of static friction of 0.2 or smaller and a surface energy of 23 to 35 mg/m^2 .

Where the transfer image on the image receiving layer is re-transferred to printing paper, etc., it is preferred that at least one image receiving layer be made of a photocuring material. A photocuring material includes a combination comprising (a) at least one photopolymerizable monomer selected from polyfunctional vinyl and/or vinylidene compounds capable of addition polymerization, (b) an organic polymer, and (c)

a photopolymerization initiator, and optionally (d) additives such as a thermal polymerization inhibitor. The polyfunctional vinyl monomers (a) include unsaturated esters of polyols, particularly acrylic or methacrylic esters (e.g., ethylene glycol diacrylate and pentaerythritol tetraacrylate).

The organic polymer (b) includes those recited above for use to form the image receiving layer. The photopolymerization initiator (c) includes ordinary photo-radical polymerization initiators, e.g., benzophenone and Michler's ketone. The initiator is usually used in an amount of 0.1 to 20% by weight based on the weight of the layer.

The thickness of the image receiving layer is generally from 0.3 to 7 μm , preferably from 0.7 to 4 μm . A thickness of 0.3 μm or larger secures sufficient film strength in re-transferring to printing paper. With a thickness of 4 μm or smaller, glossiness of the image after re-transfer to printing paper is suppressed to provide a better approximation to final prints.

A cushioning layer that is easily deformable with external stresses imposed on the image receiving layer may be provided between the substrate and the image receiving layer. A cushioning layer will improve adhesion between the image receiving layer and the image forming layer during laser writing, which leads to image quality improvement. Even when dust enters between the heat transfer sheet and the image receiving sheet,

the cushioning layer will be deformed in conformity with the contour of the dust to minimize the non-contact area of the two sheets. As a result, possible image defects, such as white spots, can be minimized in size. Furthermore, when the transfer image on the image receiving sheet is re-transferred to printing paper, etc., the image receiving layer is deformable in conformity with the surface roughness of the paper thereby to improve the transfer capabilities. The cushioning layer is also effective in controlling the glossiness of the re-transfer image and providing a better approximation to the final prints.

The cushioning layer producing these effects is preferably formed of materials having a low elastic modulus, materials having rubbery elasticity or thermoplastic resins ready to soften on heating. The cushioning layer preferably has an elastic modulus of 0.5 MPa to 1.0 GPa, particularly 1 MPa to 0.5 GPa, especially 10 to 100 MPa, at room temperature. In order for the cushioning layer to have dust or debris sinking, the cushioning layer preferably has a penetration of 10 or more as measured according to JIS K2530 (25°C, 100 g, 5 seconds). The cushioning layer preferably has a T_g of 80°C or lower, particularly 25°C or lower, and a softening point of 50° to 200°C. To control these physical properties, such as a T_g, a plasticizer may be added to the binder forming the cushioning layer.

Binders making up the cushioning layer include rubbers, such as urethane rubber, butadiene rubber, nitrile rubber,

acrylic rubber, and natural rubber, polyethylene, polypropylene, polyester, styrene-butadiene copolymers, ethylene-vinyl acetate copolymer, ethylene-acrylic copolymers, vinyl chloride-vinyl acetate copolymers, vinylidene chloride
5 resins, vinyl chloride resins containing a plasticizer, polyamide resins, and phenol resins. The thickness of the cushioning layer is usually 3 to 100 μm , preferably 10 to 52 μm , while varying depending on the kind of the binder and other conditions.

10 Although the image receiving layer and the cushioning layer must adhere to each other until completion of laser writing, the image receiving layer is preferably releasable when re-transferring the transfer image onto printing paper. To facilitate the release from the cushioning layer, a release
15 layer having a thickness of about 0.1 to 2 μm can be provided between the cushioning layer and the image receiving layer. The thickness of the release layer, which can be adjusted by proper choice of material, should be small so as not to impair the effects of the cushioning layer.

20 Binders used to form the release layer include thermoplastic resins having a T_g of 65°C or higher, such as polyolefins, polyester, polyvinyl acetal, polyvinyl formal, polyparabanic acid, polymethyl methacrylate, polycarbonate, ethyl cellulose, nitrocellulose, methyl cellulose,
25 carboxymethyl cellulose, hydroxypropyl cellulose, polyvinyl

alcohol, polyvinyl chloride, urethane resins, fluorine resins, polystyrene, acrylonitrile-styrene copolymers, crosslinking products of these resins, polyamide, polyimide, polyether-imide, polysulfone, polyether sulfone, and aramid;
5 and hardened products thereof. Commonly employed hardening agents, such as isocyanate and melamine, can be used for hardening.

The physical properties described above taken into consideration, binders preferred for making the release layer
10 are polycarbonate, acetal resins, and ethyl cellulose for their good storage stability. These binders are particularly suitable for releasing the image receiving layer comprising an acrylic resin binder.

A layer that extremely reduces in adhesion to the image
15 receiving layer on cooling can serve as a release layer. Such a layer comprises hot-melt compounds, such as waxes, and thermoplastic resins (binders) as a main ingredient. Useful hot-melt compounds are described in JP-A-63-193886. Preferred hot-melt compounds include microcrystalline wax, paraffin wax,
20 and carnauba wax. Useful thermoplastic resins include ethylene copolymers, such as ethylene-vinyl acetate copolymers, and cellulosic resins.

If desired, the above-described release layer can contain such additives as higher fatty acids, higher alcohols, higher
25 fatty acid esters, higher fatty acid amides, and higher aliphatic

amines.

A layer that melts or softens on heating and undergoes cohesive failure also serves as a release layer. A supercooling material is preferably incorporated into a release layer of
5 this kind. Useful supercooling materials include poly- ϵ -caprolactone, polyoxyethylene, benzotriazole, tribenzylamine, and vanillin.

A layer containing a compound which reduces the adhesion to the image receiving layer is also useful as a release layer.
10 Such compounds include silicone resins, e.g., silicone oil; fluorine resins, e.g., Teflon and fluorine-containing acrylic resins; polysiloxane resins; acetal resins, e.g., polyvinyl butyral, polyvinyl acetal, and polyvinyl formal; solid waxes, e.g., polyethylene wax and amide wax; and fluorine type or
15 phosphoric ester type surface active agents.

The release layer is formed by applying a solution or an emulsion (latex) of the above-mentioned material in a solvent to the cushioning layer by various techniques, such as blade coating, roll coating, bar coating, curtain coating, gravure
20 coating, hot-melt extrusion lamination, and the like. Alternatively, the solution or latex may be applied to a carrier film by the above-described application techniques to form a coating film, which is transferred to the cushioning layer.

In an embodiment of the image receiving sheet structure,
25 the image receiving layer may serve as a cushioning layer. In

this case, the image receiving sheet may have a layer structure of substrate/cushioning image receiving layer or a layer structure of substrate/undercoating layer/cushioning image receiving layer. It is preferred for the cushioning image receiving layer be provided such that it is ready to be released and transferred to printing paper. In this case, the re-transfer image will have excellent gloss. The cushioning image receiving layer usually has a thickness of 5 to 100 μm , preferably 10 to 40 μm .

It is advisable to provide a backcoating layer on the reverse side (opposite to the image receiving layer side) of the substrate to improve transport properties of the image receiving sheet in a recording apparatus. The improvement on film transport properties is ensured by adding to the backcoating layer an antistatic agent (e.g., a surface active agent or fine tin oxide particles) and/or a matting agent (e.g., silicon oxide or polymethyl methacrylate particles). According to necessity, these additives may be added to not only the backcoating layer but other layers including the image receiving layer. The kind of the additive to be added depends on the purpose. Where, for example, a matting agent is needed, a matting agent having an average particle size of 0.5 to 10 μm is added in an amount of about 0.5 to 80% by weight based on the layer to which it is added. Where an antistatic agent is needed, an appropriate compound selected from various surface active agents and

electrically conductive agents is added to reduce the surface resistivity of the layer to $10^{12} \Omega$ or lower, preferably $10^9 \Omega$ or less, at 23°C and 50% RH.

General-purpose polymers can be used as a binder of the
5 backcoating layer, including gelatin, polyvinyl alcohol, methyl cellulose, nitrocellulose, cellulose acetate, aromatic polyamide resins, silicone resins, epoxy resins, alkyd resins, phenol resins, melamine resins, fluorine resins, polyimide resins, urethane resins, acrylic resins, urethane-modified
10 silicone resins, polyethylene resins, polypropylene resins, polyester resins, Teflon resins, polyvinyl butyral resins, vinyl chloride resins, polyvinyl acetate, polycarbonate, organoboron compounds, aromatic esters, polyurethane fluoride, and polyether sulfone. Among them crosslinkable water-soluble
15 resins can be crosslinked to become a binder effective in preventing fall-off of matting agent particles, improving scratch resistance of the backcoating layer, and preventing blocking of image receiving sheets during storage. The crosslinking of the crosslinkable water-soluble resins can be
20 induced by at least one of heat, active light rays, and pressure. In some cases, an arbitrary adhesive layer may be provided between the substrate and the backcoating layer.

Organic or inorganic fine particles can be used as a matting agent added to the backcoating layer. Organic matting agents
25 include particles of polymers obtained by radical

polymerization, such as polymethyl methacrylate, polystyrene, polyethylene, and polypropylene; and condensed polymers, such as polyester and polycarbonate.

The backcoating layer preferably has a coating weight
5 of about 0.5 to 5 g/m². A coating film thinner than 0.5 g/m² is difficult to form stably and tends to allow matting agent particles to fall off. If the coating thickness exceeds 5 g/m², the matting agent present therein must have a considerably large particle size to exhibit its effect. Such large particles in
10 the backcoating layer will imprint themselves on an adjacent image receiving layer in a roll form. It would follow that the transfer image on the image receiving layer may suffer from image deficiency or unevenness on account of the imprinted surface unevenness particularly where the image forming layer
15 is very thin.

It is preferred for the matting agent used in the backcoating layer to have a number-average particle size greater than the thickness of the particle-free area of the backcoating layer by 2.5 to 20 μm. It is necessary that matting agent
20 particles of 8 μm or greater be present in the backcoating layer in an amount of 5 mg/m² or more, particularly 6 to 600 mg/m², thereby to reduce troubles due to foreign matter. In order to prevent image defects attributed to extraordinary large particles and to obtain desired performance with a reduced amount
25 of a matting agent, it is preferred to use a matting agent whose

sizes are narrowly distributed with a coefficient of variation σ/\bar{r}_n (obtained by dividing a standard deviation of a distribution by a mean) of 0.3 or smaller, preferably 0.15 or smaller.

The backcoating layer preferably contains an antistatic
5 agent to prevent foreign matter attraction due to triboelectricity. A wide range of known antistatic agents can be used, such as cationic, anionic or nonionic surface active agents, polymeric antistatics, electrically conductive particles, and those described in *11290 no Kagaku Syohin*, Kagaku
10 Kogyo Nipposha, 875-876. Of these antistatic agents suitable for use in the backcoating layer are electrically conductive materials, such as carbon black, metal oxides, e.g., zinc oxide, titanium oxide, and tin oxide, and organic semiconductors. Electrically conductive fine particles are particularly
15 preferred, for they do not separate from the backcoating layer to exert stable and environment-independent antistatic effects.

The backcoating layer can further contain various activators or release agents, such as silicone oil and fluorine
20 resins, for improving coating capabilities or releasability. It is especially advisable to provide the above-described backcoating layer where the cushioning layer and the image receiving layer have a softening point of 70°C or lower measured by thermochemical analysis (hereinafter referred to as a TMA
25 softening point). The TMA softening point is obtained by

observing the phase of a sample being heated at a given rate of temperature rise with a given load applied thereto. In the present invention, the temperature at which the phase of the sample begins to change is defined as a TMA softening point.

5 Measurement of a TMA softening point can be made with, for example, Thermoflex supplied by Rigaku Denki-Sha.

In carrying out thermal transfer recording, the heat transfer sheet and the image receiving sheet are superposed on each other to prepare a laminate with the image forming layer of the former and the image receiving layer of the latter in
10 contact.

A laminate of the heat transfer sheet and the image receiving sheet can be prepared through various methods. For example, the two sheets superposed on each other in the
15 above-described manner are passed through a pair of pressure and heat rollers. The heating temperature of the rollers is 160°C or lower, preferably 130°C or lower.

Another method of preparing the laminate is vacuum holding, which has previously been described with respect to the recording
20 apparatus. That is, the image receiving sheet is the first to be held by suction around a recording drum having a number of suction holes. The heat transfer sheet, which is designed to be slightly larger in size than the image receiving sheet, is then held on the image receiving sheet while the entrapped
25 air is pressed out with a squeegee roller. Still another method

of preparing the laminate comprises pulling the image receiving sheet to a recording drum, mechanically fixing the sheet onto the drum, and then fixing the heat transfer sheet thereon in the same manner as for the image receiving sheet. The vacuum
5 holding method is especially advantageous in that temperature control (as required for heat rollers) is unnecessary, and uniform contact of the two sheets is accomplished quickly.

10

EXAMPLES

The present invention will now be illustrated in greater detail with reference to Examples, but it should be understood that the invention is not deemed to be limited thereto. Unless
15 otherwise noted, all the parts and percents are by weight.

EXAMPLE 1

1. Preparation of heat transfer sheet (C)

1-1. Formation of backcoating layer

20 A coating composition for 1st backcoating layer was prepared according to the following formulation.

Formulation of coating composition for 1st backcoating layer:

Aqueous dispersion of acrylic resin (Jurymer ET410, available from Nihon Junyaku Co., Ltd.; solid content:	
25 20%)	2 parts

Antistatic agent (waterborne dispersion of tin oxide-antimony oxide; average particle size: 0.1 μm ; solid content: 17%) 7.0 parts

Polyoxyethylene phenyl ether 0.1 part

5 Melamine compound (Sumitex Resin M-3, from Sumitomo Chemical Co., Ltd.) 0.3 parts

Distilled water to make 100 parts

A biaxially stretched polyethylene terephthalate (PETP) film having a thickness of 75 μm and an Ra of 0.01 μm on both
10 sides was subjected to corona discharge treatment on one side. The coating composition for 1st backcoating layer was applied to the corona discharge treated side of the substrate to a dry thickness of 0.03 μm and dried at 180°C for 30 seconds to form a first backcoating layer. The substrate used had a Young's
15 modulus of 450 kg/mm^2 (≈ 4.4 GPa) in the MD and of 500 kg/mm^2 (≈ 4.9 GPa) in the TD; an F-5 value of 10 kg/mm^2 (≈ 98 MPa) in the MD and of 13 kg/mm^2 (≈ 127.4 MPa) in the TD; a thermal shrinkage percentage of 0.3% in the MD and of 0.1% in the TD both after heating at 100°C for 30 minutes; a breaking strength of 20 kg/mm^2
20 (≈ 196 MPa) in the MD and of 25 kg/mm^2 (≈ 245 MPa) in the TD; and an elastic modulus of 400 kg/mm^2 (≈ 3.9 GPa).

A coating composition for second backcoating layer was prepared according to the following formulation.

Formulation of coating composition for 2nd backcoating layer:

25 Polyolefin (Chemipearl S-120, available from Mitsui

	Chemicals, Inc.; solid content: 27%)	3.0 parts
	Antistatic agent (waterborne dispersion of tin oxide-antimony oxide; average particle size: 0.1 μ m; solid content: 17%)	2.0 parts
5	Colloidal silica (Snowtex C, available from Nissan Chemical Industries, Ltd.; solid content: 20%)	
		2.0 parts
	Epoxy compound (Denacol EX-614B, from Nagase Chemical Co., Ltd.)	0.3 parts
10	Distilled water	To make 100 parts
	The coating composition for second backcoating layer was applied to the first backcoating layer to a dry thickness of 0.03 μ m and dried at 170°C for 30 seconds to form a second backcoating layer.	
15	1-2. Formation of light-heat conversion layer	
	The components shown below were mixed while agitating with a stirrer to prepare a coating composition for light-heat conversion layer.	
20	Formulation of coating composition for light-heat conversion layer:	
	Infrared absorbing dye (compound (I'-17) of formula (B) :	
		7.6 parts
	Polyamide-imide of formula (A) wherein R is a linking	
25	group (6)	29.3 parts

	Exxon Naphtha	5.8 parts
	N-Methylpyrrolidone	1500 parts
	Methyl ethyl ketone (MEK)	360 parts
	Fluorine type surface active agent (Magafac F-176PF, from	
5	Dainippon Ink & Chemicals, Inc.)	0.5 parts
	Matting agent dispersion	14.1 parts

The matting agent dispersion used in the above formulation was prepared as follows. A mixture of 10 parts of true spherical silica powder having an average particle size of 1.5 μm (Seahostar KE-P150, from Nippon Shokubai Co., Ltd.), 2 parts of an acrylic ester-styrene copolymer as a dispersant (Joncryl 611, from Johnson Polymer Co., Ltd.), 16 parts of MEK, and 64 parts of N-methylpyrrolidone was put in a 200 ml polyethylene container together with 30 parts of glass beads having a diameter of 2 mm. The mixture in the container was dispersed in a paint shaker supplied by Toyo Seiki Co., Ltd. for 2 hours to prepare a matting agent dispersion.

The resulting coating composition was applied to the other side of the PETP film with a wire bar and dried in an oven at 120°C for 2 minutes to form a light-heat conversion layer. The light-heat conversion layer had an optical density (OD_{LH}) of 0.93 at 808 nm as measured with a UV spectrophotometer UV-240 supplied by Shimadzu Corp. A cut area of the light-heat conversion layer was observed under a scanning electron microscope (SEM) to find that the average layer thickness (T_{LH})

was 0.3 μm . The surface gloss of the light-heat conversion layer was 90 (Gs (60°C) as specified in JIS Z8741).

1-3. Formation of trapping layer (intermediate layer)

5 A coating composition for trapping layer was prepared by mixing the following components by agitating with a stirrer.

Formulation of coating composition for trapping layer:

	MEK	38.4 parts
	Cyclohexanone	9.6 parts
10	Modified cellulose (AS-MG, from Shin-Etsu Chemical Co., Ltd.)	0.5 parts
	Surface active agent (Megafac F-176PF, from Dainippon Ink & Chemicals, Inc.)	0.01 part

15 The resulting coating composition was applied to the light-heat conversion layer with a wire bar and dried in an oven at 120°C for 2 minutes to form a trapping layer having a thickness of 0.1 μm in average.

20 1-4. Formation of image forming layer

The components shown below were mixed by agitating with a stirrer to prepare a coating composition for cyan image forming layer.

Formulation of cyan image forming layer:

25 Potassium N-perfluorooctanesulfonyl-N-propylglycine

	(surface active agent)	0.12 parts
	Surfynol 504 (surface active agent, available from Nisshin Chemical Industry Co., Ltd.)	0.30 parts
	Ion exchanged water	208 parts
5	Vinyblan 2561 (aqueous latex of a styrene-acrylic copolymer resin; from Nisshin Chemical Industry Co., Ltd.; MFT: 0°C; Tg: -36°C)	17.1 parts
	Himicron K Blue 6227 (available from Mikuni color Ltd.)	8.4 parts

10

The coating composition for a cyan image forming layer was applied to the trapping layer with a wire bar for 1 minute and dried in an oven at 100°C for 2 minutes to form a cyan image forming layer. There was thus obtained a heat transfer sheet

15 (C) having a layer structure of substrate/light-heat conversion layer/trapping layer/cyan image forming layer in the order described. The cyan image forming layer had a thickness of 0.45 μm in average and a surface hardness of 200 g or more as measured with a sapphire stylus.

20

2. Preparation of image receiving sheet

A coating composition for cushioning layer and a coating composition for image receiving layer were prepared according to the following formulations.

25 Formulation of coating composition for cushioning layer:

	Vinyl chloride-vinyl acetate copolymer as binder (MPR-TSL, available from Nisshin Chemical Industry Co., Ltd.)	20 parts
5	Plasticizer (Paraplex G-40, available from The C.P. Hall Co.)	10 parts
	Fluorine-type surface active agent (Megafac F-177, available from Dainippon Ink & Chemicals, Inc.)	0.5 parts
10	Antistatic agent (SAT-5 Supper (IC), quaternary ammonium salt available from Nihon Jinyaku Co., Ltd.)	0.3 parts
	MEK	60 parts
	Toluene	10 parts
	N,N-Dimethylformamide	3 parts
15	Formulation of coating composition for image receiving layer:	
	Polyvinyl butyral (S-LEC B BL-SH, available from Sekisui Chemical Co., Ltd.)	8 parts
	Antistatic agent (Sanstat 2012A, available from Sanyo Chemical Industries, Ltd.)	0.7 parts
20	Surface active agent (Megafac F-176PF, from Dainippon Ink & Chemicals, Inc.; solid content: 20%)	0.1 part
	n-Propyl alcohol	20 parts
	Methanol	20 parts
	1-Methoxy-2-propanol	50 parts

25

The coating composition for cushioning layer was applied to a white PETP film having a thickness of 130 μm (Lumirror #130E58, available from Toray Industries, Inc.) with a small-width applicator to a dry thickness of about 20 μm and dried to form a cushioning layer. The coating composition for image receiving layer was applied thereon to a dry thickness of about 2 μm and dried to form an image receiving layer. The white PETP film used as a substrate is a void-containing PETP layer (thickness: 116 μm ; void: 20%) laminated on both sides thereof with a titanium oxide-containing PETP layer (thickness: 7 μm ; titanium oxide content: 2%) (total thickness: 130 μm ; specific gravity: 0.8).

Each of the resulting heat transfer sheet (C) and the image receiving sheet was wound into a roll and stored at room temperature for one week before image formation.

The resulting image receiving layer had an R_a of 0.02 μm (a preferred R_a is 0.01 to 0.4 μm), a surface waviness of 1.2 μm (a preferred surface waviness is 2 μm or smaller), a smoother value of 0.8 mmHg (≈ 0.11 kPa) (at 23°C and 55%RH), a coefficient of static friction of 0.37 (a preferred coefficient of static friction is 0.8 or smaller), a surface energy of 29 mJ/m², and a water contact angle of 85°C.

EXAMPLES 2 TO 4 AND COMPARATIVE EXAMPLES 1 TO 3

Heat transfer sheets (C) were prepared in the same manner

as in Example 1, except for using each of the waterborne latices shown in Table 1 below as a binder of the image forming layer.

Each of the resulting cyan image forming materials was evaluated as follows. Image formation by thermal transfer and re-transfer to printing paper were carried out in accordance with the scheme of the system configuration shown in Fig. 4, in which Luxel FINALPROOF 5600 was used as a laser thermal transfer recording apparatus.

A 56 cm wide and 79 cm long cut sheet of the image receiving sheet was held by suction on a recording drum having a diameter of 380 mm (a preferred drum diameter is 360 mm or greater) through suction holes of 1 mm in diameter of the drum (one hole per 3 cm by 8 cm area). A 61 cm wide and 84 cm long cut sheet of the heat transfer sheet (C) was superposed on the image receiving sheet with its four edges extending evenly from the edges of the image receiving sheet while being squeegeed with a squeegee roller so that the two sheets were brought into intimate contact while allowing entrapped air to escape and be sucked. The degree of vacuum of the drum, measured with the suction holes closed, was (atmospheric pressure minus 150) mmHg (≈ 81.13 kPa). The drum was rotated, and the heat transfer sheet was scanned with semiconductor laser light having a wavelength of 808 nm and a spot diameter of 7 μ m on the surface of the light-heat conversion layer. The laser was moved in a direction (slow scan direction) perpendicular to the drum

rotating direction (fast scan direction) to carry out recording of a solid cyan image. The laser recording conditions are shown below. The light source was multibeam arranged in a two-dimensional parallelogram consisting of five lines of laser beams arrayed in the fast scan direction and three rows of laser beams arrayed in the slow scan direction.

Laser power: 110 mW

Drum rotation: 500 rpm

Slow scanning pitch: 6.35 μ m

Environment: (1) 20°C, 40% RH, (2) 23°C, 50% RH, (3) 26°C, 65% RH

The recorded image size was 515 mm wide and 728 mm long, and the resolution was 2600 dpi.

After completion of laser recording, the laminate was removed from the drum, and the heat transfer sheet (C) was stripped by hand off the image receiving sheet to transfer the solid cyan image to the image receiving sheet. The image on the image receiving sheet was then re-transferred to a sheet of printing paper (Reflection II, available from Stora Enso) by use of a thermal transfer apparatus having the following specification to obtain a solid cyan image. The dynamic frictional coefficient of the insertion table against a PETP film (the substrate of the image receiving sheet) was 0.1 to 0.7. The speed of transporting the laminate (image receiving sheet and the printing paper) was 15 to 50 mm/sec. The heat

rolls were made of a material having a Vickers hardness of 70 (a preferred Vickers hardness of the material is 10 to 100).

It was proved as a result that all the heat transfer sheets provide a high quality image with a stable transfer density even in high-energy laser recording using a multibeam laser writing system under various temperature and humidity conditions.

The heat transfer sheets of Examples and Comparative Examples were also evaluated as follows. The results obtained are shown in Table 1.

1) Surface condition of image forming layer

The surface condition of the cyan image forming layer of each heat transfer sheet (C) was observed with the naked eye and rated according to the following standard.

A: Uniform

B: Almost uniform

C: Slight thickness variation

D: Non-uniform with considerable thickness variation

2) Dot reproduction

Dot reproduction in the transferred image was evaluated under microscopic observation and rated according to the following standard.

A: Sharp dots are reproduced over a full range from highlights to shadows.

B: Substantially sharp dots are reproduced over a full range

from highlights to shadows.

C: Dots are reproduced over a full range from highlights to shadows, but many dots are found missing.

D: Dots reproduction is unsatisfactory.

*1: Waterborne latex of styrene-acrylic copolymer resin from Nisshin Chemical Industry Co., Ltd. (hereinafter, "Nisshin").

*2: Waterborne latex of acrylic resin from Nisshin.

10 *3: Waterborne latex of acrylic resin from Nisshin.

*4: Waterborne latex of acrylic resin from Nisshin.

*5: Waterborne latex of ethylene-vinyl acetate copolymer resin from Sumitomo Chemical Co., Ltd.

*6: Waterborne latex of SBR from Zeon Corp.

15

As is apparent from Table 1, the image forming materials of the present invention are satisfactory in both coating surface condition of image forming layer and dot reproduction in

transferred image.

It has also confirmed that the image forming materials of the invention are applicable to an on-demand image recording system and capable of providing an image with clear hue and
5 good dot reproduction in the on-demand system as well.

The present invention provides a thermal transfer image forming material capable of recording a high quality image. The image forming layer of the image forming material has a satisfactory surface condition and exhibits excellent image
10 forming performance in sensitivity and image quality. The technique of the invention is applicable to on-demand image recording, making it possible to record an image of desired color when needed without holding a large stock of heat transfer sheets of various colors.

15

This application is based on Japanese Patent application JP 2003-58581, filed March 5, 2003, the entire content of which is hereby incorporated by reference, the same as if set forth at length.
